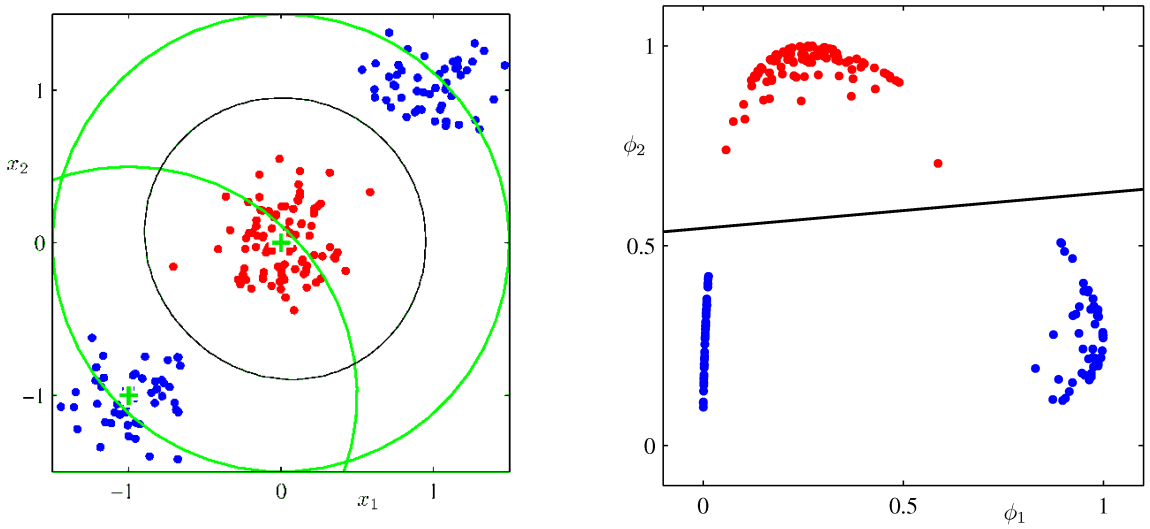
Galen Group
INRIA-Saclay

Beyond linear boundaries

- Straighftorward extension: More features



- Which features?
- How can we control complexity?

Last lecture: Kernel trick

Define Kernel: $K(\mathbf{x}, \mathbf{y}) = < \phi(\mathbf{x}), \phi(\mathbf{y}) >$

Rewrite everything with kernels: same optimization in the dual!

$$\max_{\mu} \quad \sum_{i=1}^{M} \mu_i - \frac{1}{2} \sum_{i=1}^{M} \sum_{j=1}^{M} y^i y^j \mu_i \mu_j K(\mathbf{x}^i, \mathbf{x}^j)$$

$$s.t. \quad 0 \leq \mu_i \leq C$$

$$\sum_{i=1}^{M} \mu_i y^i = 0$$

Classifier: $y = \text{sign}(\sum_{i=1}^{M} \mu_i y^i K(\mathbf{x}^i, \mathbf{x}) + b)$

Complexity of evaluation: O(#Support Vectors)

Lecture outline

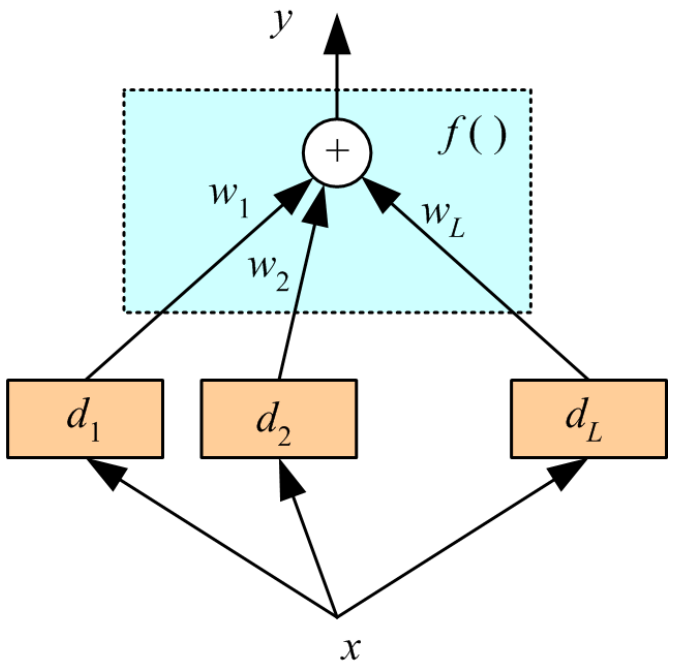
Adaboost

Decision Trees

Random Forests

Voting Methods

- Give up idea of building `the' classifier
- Generate a group of base-learners which has higher accuracy when combined
- Main tasks
  - Generating the learners
  - Combining them



Why should this work?

- Committee of M predictors for target output $y_{COM}(\mathbf{x}) = \frac{1}{M}\sum_{m=1}^{M} y_m(\mathbf{x})$
- Output: true value + error $y(\mathbf{x}) = h(\mathbf{x}) + \epsilon(\mathbf{x})$
- Average sum of squares error for m-th expert:

$$\mathbb{E}_{\mathbf{x}} = \left[\{y_m(\mathbf{x}) - h(\mathbf{x})\}^2\right] = \mathbb{E}_{\mathbf{x}}\left[\epsilon_m(\mathbf{x})^2\right]$$

- Average error of individual members: $\mathbb{E}_{AV} = \frac{1}{M}\sum_{m=1}^{M} \mathbb{E}_{\mathbf{x}}\left[\epsilon_m(\mathbf{x})^2\right]$
- Average error of committee:

$$\mathbb{E}_{COM} = \mathbb{E}_{\mathbf{x}}\left[\left\{\frac{1}{M}\sum_{m=1}^{M} y_m(\mathbf{x}) - h(\mathbf{x})\right\}^2\right] = \mathbb{E}_{\mathbf{x}}\left[\left\{\frac{1}{M}\sum_{m=1}^{M} \epsilon_m(\mathbf{x})\right\}^2\right]$$

- If errors have zero mean and are uncorrelated: $\mathbb{E}_{\mathbf{x}}\left[\epsilon_m(\mathbf{x})\right] = 0$

$$\mathbb{E}_{\mathbf{x}}\left[\epsilon_m(\mathbf{x})\epsilon_j(\mathbf{x})\right] = 0$$

then $\mathbb{E}_{COM} = \frac{1}{M}\mathbb{E}_{AV}$

Boosting Idea

- General algorithm
  - Iterate
    - Pick subset of training data
    - Obtain weak learner
      - Easy to train and evaluate
  - Output final classifier by majority voting of the weak learners

Adaboost

- Adaptive Boosting
  - `A decision theoretic generalization of on-line learning and an application to boosting', Freund and Schapire '95
    - ~5500 Citations
  - Versatile (Discrete data, arbitrary distributions, multi-class, regression)
  - Very easy to program
  - Excellent results
- Defines a classifier using an additive model (weighted voting):

$$F(x) = \alpha_1 f_1(x) + \alpha_2 f_2(x) + \alpha_3 f_3(x) + \ldots$$

Strong classifier

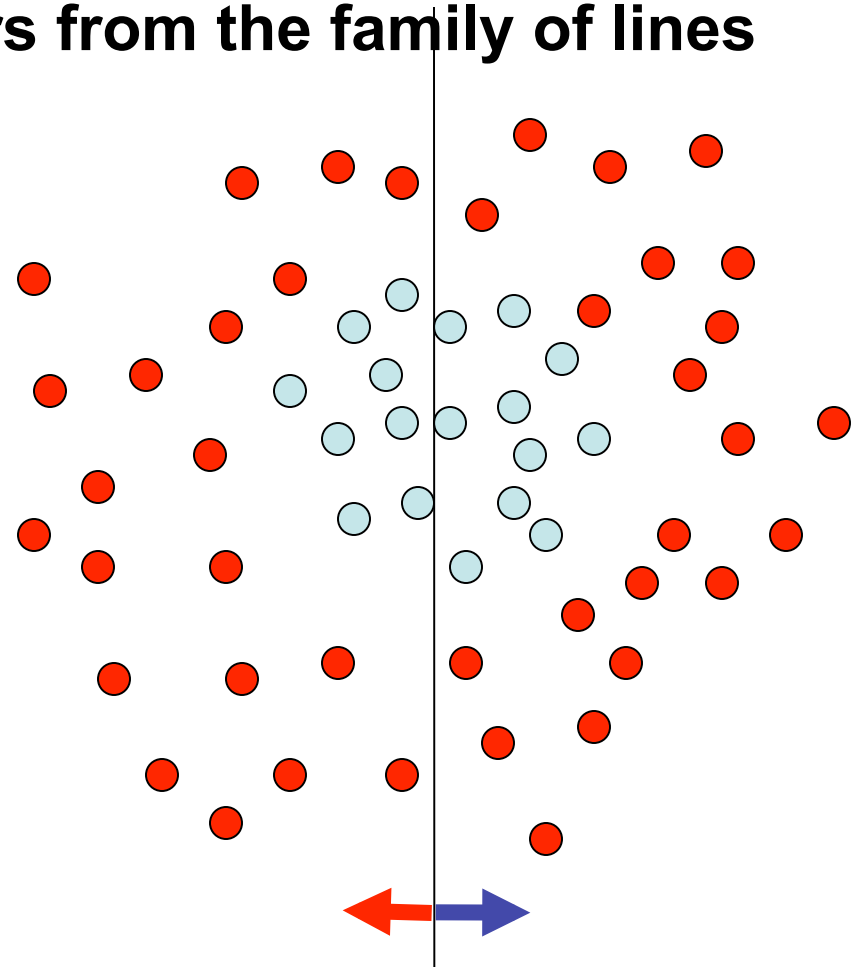
Toy example

Weak learners from the family of lines



Each data point has a class label:

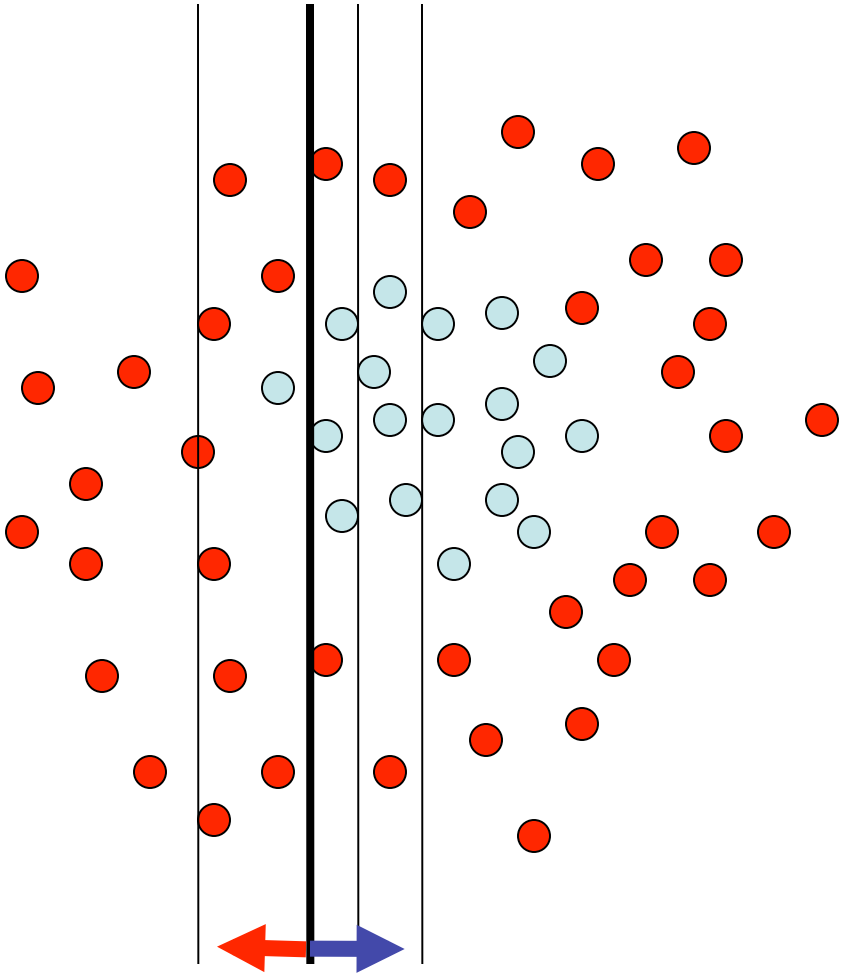
$$y_t = \begin{cases} +1 & (\bullet) \\ -1 & (\circ) \end{cases}$$

and a weight:

$$w_t = 1$$

h => p(error) = 0.5 it is at chance

Toy example



Each data point has a class label:

$$y_t = \begin{cases} +1 & (\bullet) \\ -1 & (\circ) \end{cases}$$

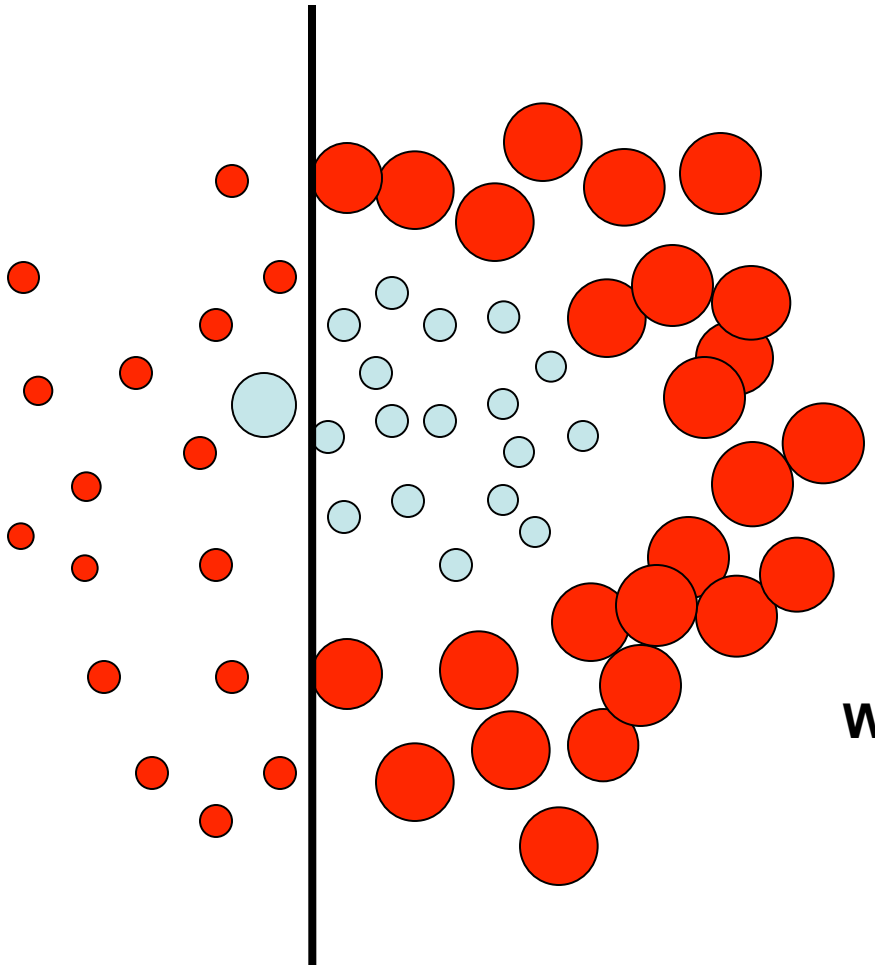
and a weight:

$$w_t = 1$$

This one seems to be the best

This is a ‘weak classifier’: It performs slightly better than chance.

Toy example



Each data point has a class label:

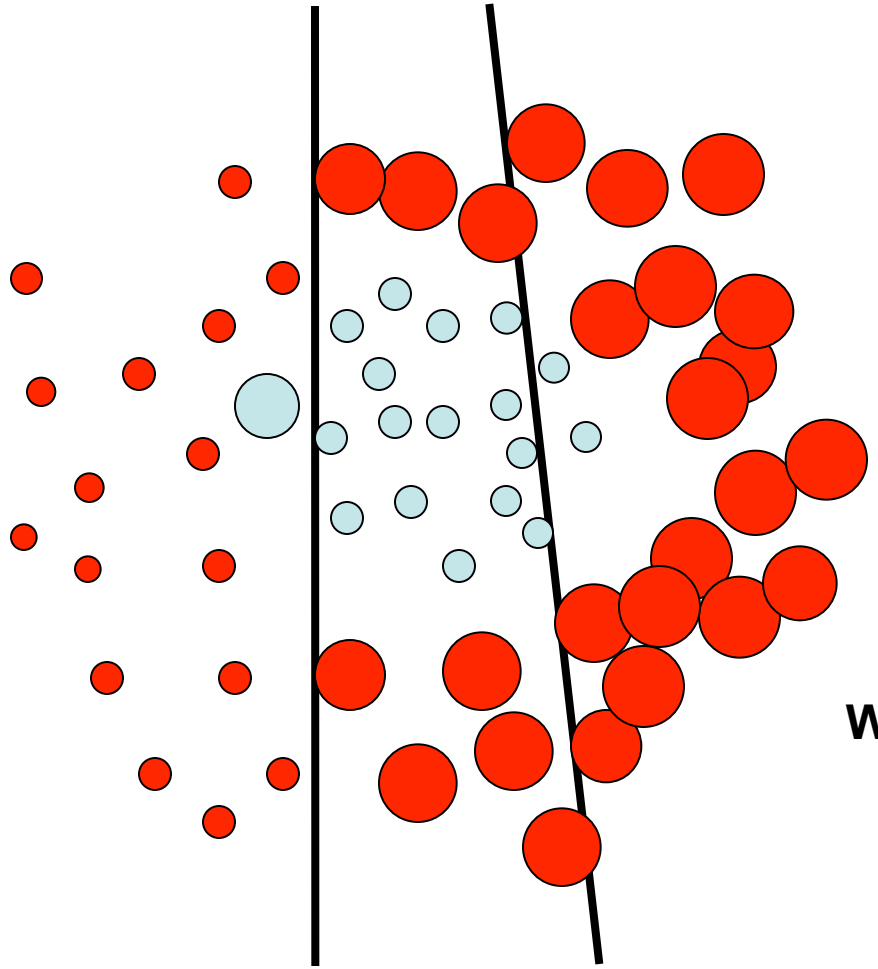
$$y_t = \begin{cases} +1 & (\bullet) \\ -1 & (\circ) \end{cases}$$

We update the weights:

$$w_t \leftarrow w_t \exp\{-y_t H_t\}$$

We set a new problem for which the previous weak classifier performs at chance again

Toy example



Each data point has a class label:

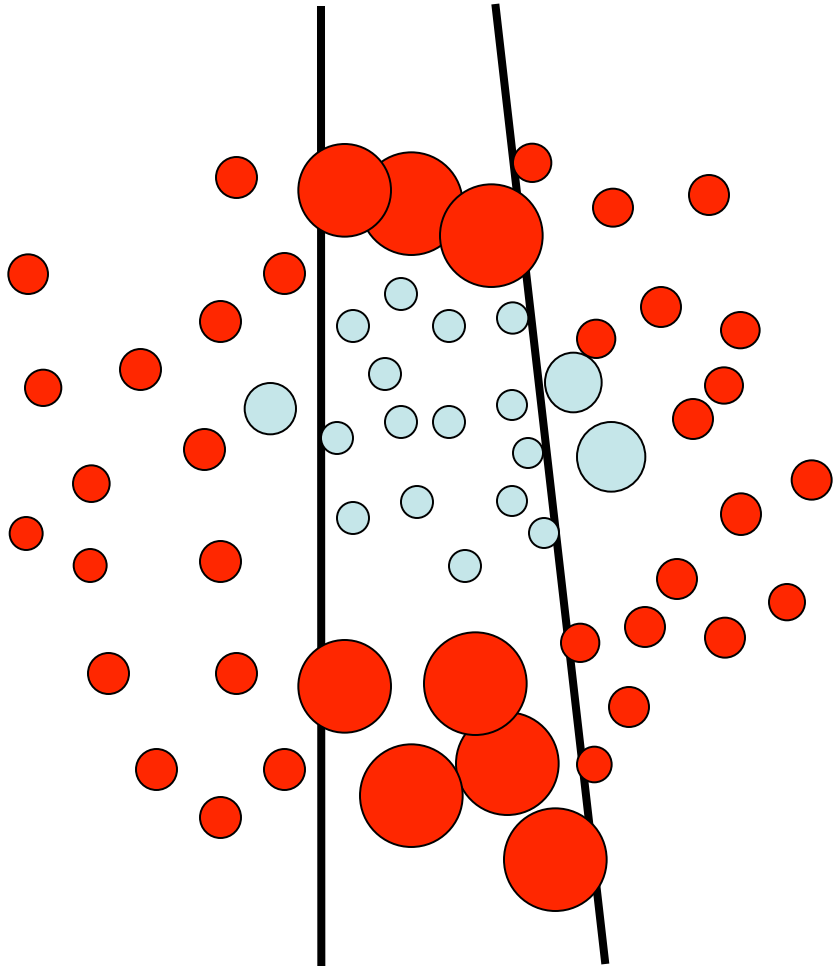
$$y_t = \begin{cases} +1 & (\bullet) \\ -1 & (\circ) \end{cases}$$

We update the weights:

$$w_t \leftarrow w_t \exp\{-y_t H_t\}$$

We set a new problem for which the previous weak classifier performs at chance again

Toy example



Each data point has a class label:

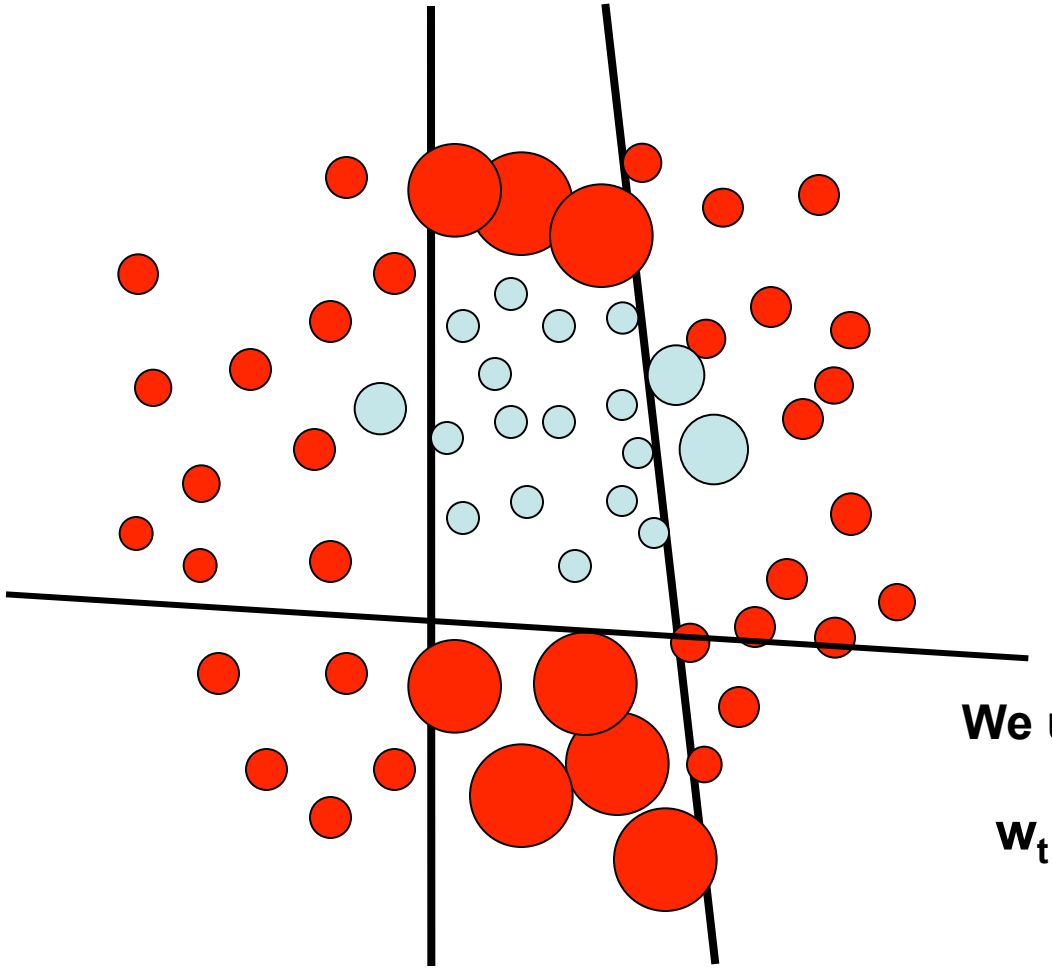
$$y_t = \begin{cases} +1 & (\bullet) \\ -1 & (\circ) \end{cases}$$

We update the weights:

$$w_t \leftarrow w_t \exp\{-y_t H_t\}$$

We set a new problem for which the previous weak classifier performs at chance again

Toy example



Each data point has a class label:

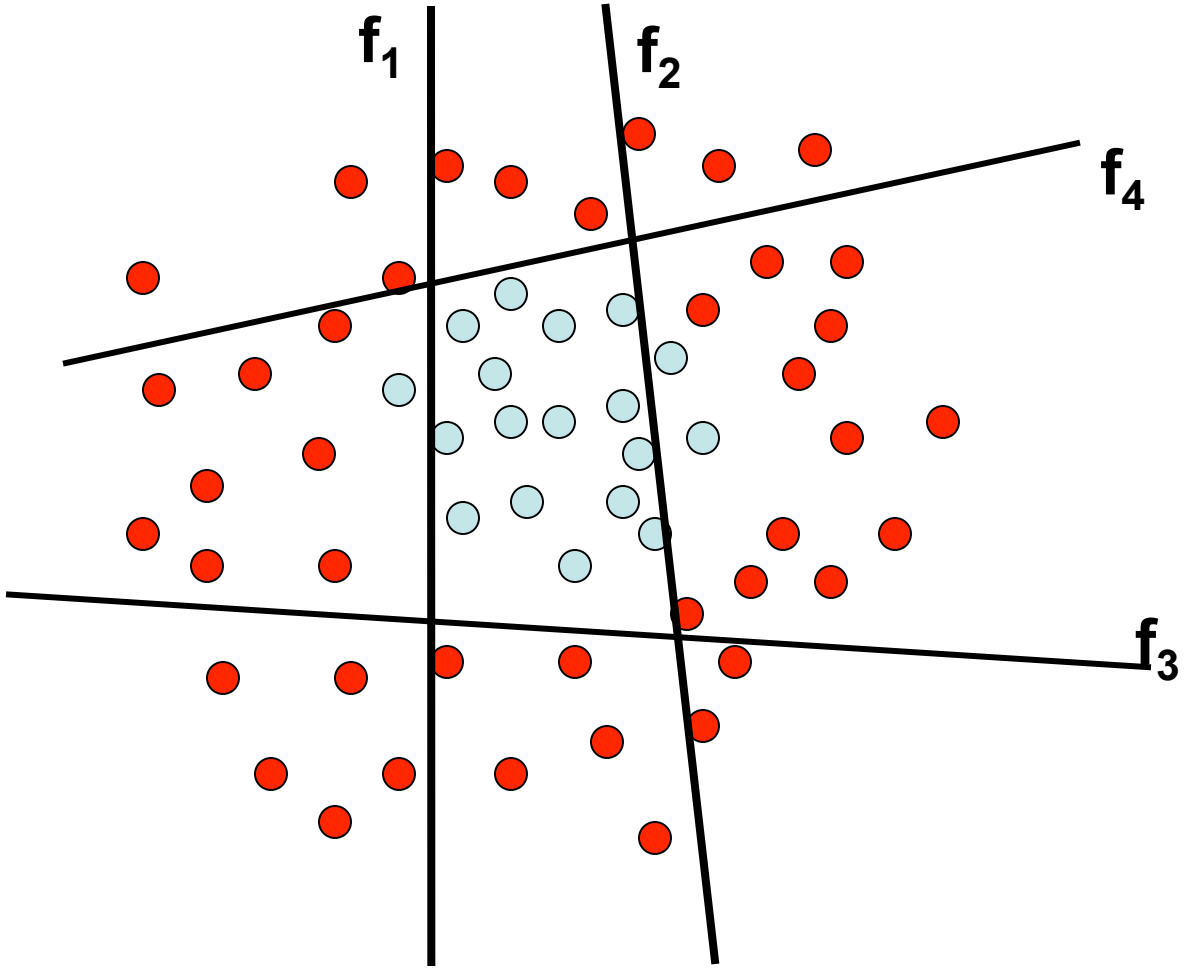
$$y_t = \begin{cases} +1 & (\bullet) \\ -1 & (\circ) \end{cases}$$

We update the weights:

$$w_t \leftarrow w_t \exp\{-y_t H_t\}$$

We set a new problem for which the previous weak classifier performs at chance again

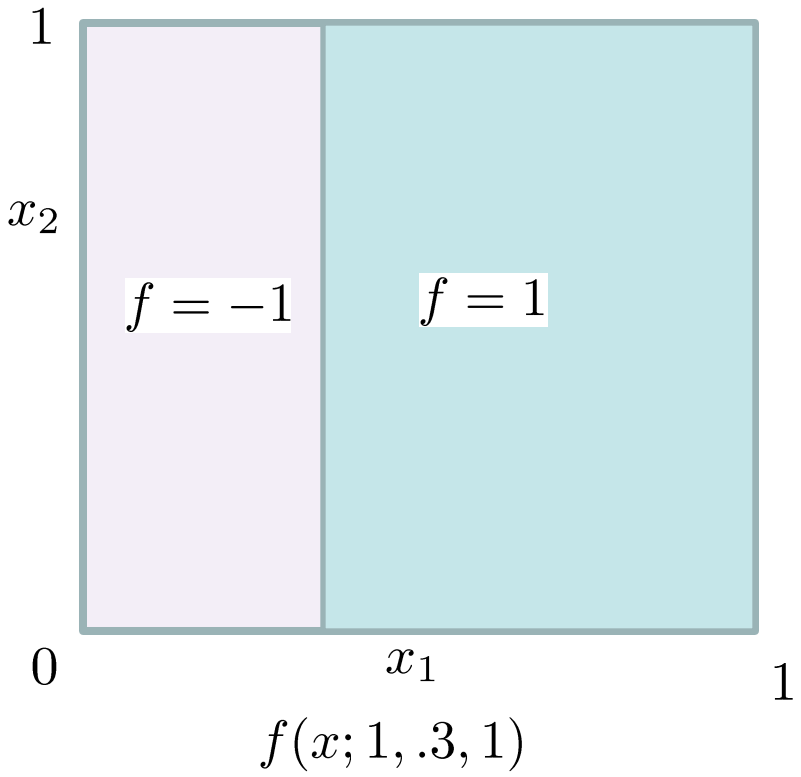
Toy example



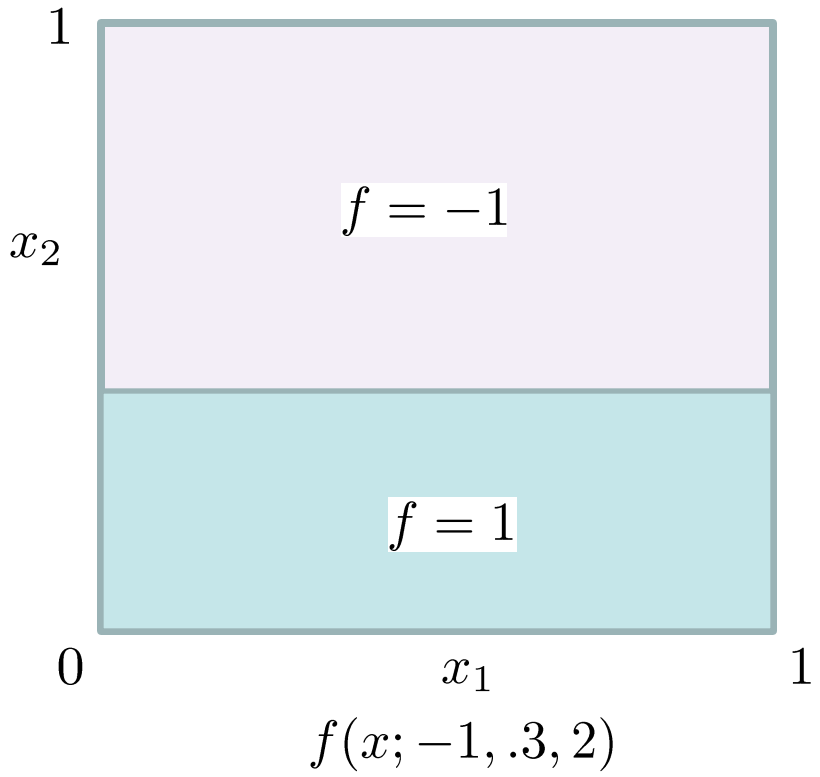
The strong (non- linear) classifier is built as the combination of all the weak (linear) classifiers.

Weak Learner Example

- Decision stump $f(x; s, \theta, i) = 2s[x_i > \theta] - s, \quad s \in \{-1, 1\}$



$f(x; 1, .3, 1)$



$f(x; -1, .3, 2)$

  - Extremely easy to train and evaluate

Adaboost Algorithm

- Given: $(x^i, y^i), x^i \in \mathcal{X}, y^i \in \{-1, 1\}, i = 1, \ldots, N$
- Initialize: $D_1(i) = \frac{1}{N}$
- For $t = 1 \ldots T$
  - Find classifier $h_t : \mathcal{X} \rightarrow \{-1, 1\}$ with smallest weighted error

$$\epsilon_t = \frac{\sum_{i=1}^{N} D_t^i [y^i \neq h_t(x^i)]}{\sum_i D_t^i}$$

  - Update distribution

$$D_{t+1}^i = \frac{D_t^i}{Z_t} \times \begin{cases} \exp(-\alpha_t), & \text{if} y^i = h_t(x^i) \\ \exp(\alpha_t), & \text{if} y^i \neq h_t(x^i) \end{cases}$$

$$= \frac{D_t^i}{Z_t} \exp(-\alpha_t y^i h_t(x^i))$$

$$a_t = \frac{1}{2} \log \frac{(1-\epsilon_t)}{\epsilon_t}$$

$$Z_t = \sum_i D_t^i \exp(-\alpha_t y^i h_t(x^i))$$

- Final classifier

$$H(x) = \text{sign}\left(\sum_t a_t h_t(x)\right)$$

When and why does this work?

- Introduce `edge': $\epsilon_t = \frac{1}{2} - \underbrace{\gamma_t}_{\text{Edge}}$
- Theorem:

$$\underbrace{\sum_{i=1}^{N} \frac{1}{N}[y^i \neq H(x^i)]}_{\text{Final Training Error}} \leq \prod_{t=1}^{T} \left[2\sqrt{\epsilon_t(1-\epsilon_t)}\right]$$

$$= \prod_{t=1}^{T} \sqrt{1-4\gamma_t^2}$$

$$\leq \exp\left(-2\sum_{t=1}^{T}\gamma_t^2\right)$$

- Assumption $\gamma_t \geq \gamma > 0, \quad \forall t$

$$\sum_{i=1}^{N} \frac{1}{N}[y^i \neq H(x^i)] \leq \exp(-2T\gamma^2)$$

Step I: Relate weights with vote

- Recursion for D

$$
\begin{aligned}
D_{t+1}^i &= \frac{D_t^i}{Z_t}\exp(-\alpha_t y^i h_t(x^i)) \\
&= \frac{\frac{D_{t-1}^i}{Z_{t-1}}\exp(-\alpha_{t-1} y^i h_{t-1}(x^i))}{Z_t}\exp(-\alpha_t y^i h_T(x^i)) \\
&= \frac{D_{t-1}}{Z_t Z_{t-1}}\exp\left(-\left[\alpha_t y^i h_t(x^i) + \alpha_{t-1} y^i h_{t-1}(x^i)\right]\right) \\
&= \frac{1}{N}\frac{\exp\left(-y^i \sum_{k=1}^t \alpha_k h_k(x^i)\right)}{\prod_{k=1}^t Z_k}
\end{aligned}
$$

- So

$$
D_{T+1}^i = \frac{1}{N}\frac{\exp\left(-y^i f(x^i)\right)}{\prod_{k=1}^T Z_k}
$$

Step II: Bound training error in terms of Z

- Lower bound for error

$$\sum_{i=1}^{N} \frac{1}{N}[y^i \neq H(x^i)] \overset{H(x)=\text{sign}f(x)}{=} \frac{1}{N}\sum_i \begin{cases} 1 & y^i f(x^i) \leq 0 \\ 0 & y_i f(x_i) > 0 \end{cases}$$

$$\leq \sum_{i=1}^{N} \frac{1}{N} \exp(-y^i f(x^i))$$

$$= \sum_{i=1}^{N} D_{T+1}^i \prod_{k=1}^{T} Z_k$$

$$= 1 \prod_{k=1}^{T} Z_k$$

Step III: Relate Z with ε

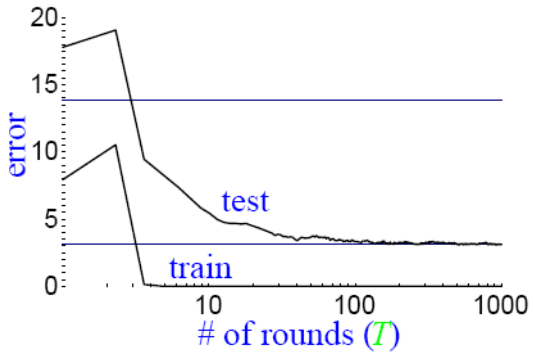
- We set out to show $$\sum_{i=1}^{N} \frac{1}{N}[y^i \neq H(x^i)] \leq \prod_{t=1}^{T} \left[2\sqrt{\epsilon_t(1-\epsilon_t)}\right]$$
- So far we have shown $$\sum_{i=1}^{N} \frac{1}{N}[y^i \neq H(x^i)] \leq \prod_{t=1}^{T} Z_k$$
- But

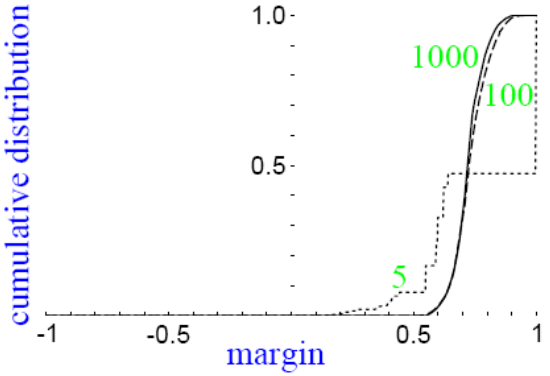
$$\begin{aligned} Z_t &= \sum_{i=1}^{N} D_t^i \exp(-\alpha_t y^i h_t(x^i)) \\ &= \sum_{i:y^i \neq h_t(x^i)} D_t^i \exp(-\alpha_t y^i h_t(x^i)) + \sum_{i:y^i = h_t(x^i)} D_t^i \exp(-\alpha_t y^i h_t(x^i)) \\ &= \sum_{i:y^i \neq h_t(x^i)} D_t^i \exp(\alpha_t) + \sum_{i:y^i = h_t(x^i)} D_t^i \exp(-\alpha_t) \\ &= (\epsilon_t)\exp(\alpha_t) + (1-\epsilon_t)\exp(-\alpha_t) \\ \alpha=\tfrac{1}{2}\log(\tfrac{1-\epsilon}{\epsilon}) \quad &= \epsilon_t \frac{\sqrt{1-\epsilon_t}}{\sqrt{\epsilon_t}} + (1-\epsilon_t)\frac{\sqrt{\epsilon_t}}{\sqrt{1-\epsilon_t}} \\ &= 2\sqrt{\epsilon_t(1-\epsilon_t)} \end{aligned}$$

- Q.E.D. = Quite Easily Done ☺

Generalization Error for Adaboost

- **Empirical Evidence**





- **Theoretical Justification:**
  - **Margin of example i:** $y_i f(x_i)$
  - **Adaboost is increasing the margins of the training set**
  - **Large margin classifiers lead to good generalization (next lecture)**

Optimization perspective of Adaboost

- Each round minimizes $\sum_{i=1}^{N} \exp(-y^i f(x^i))$ by fitting an additive model

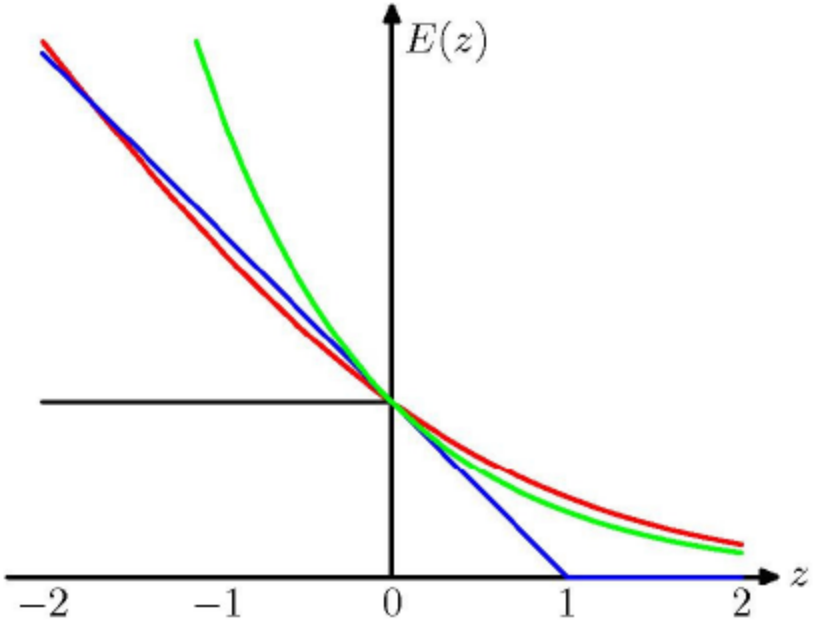
$$f'(x) = f(x) + \alpha h(x)$$

- Proof:

$$\begin{aligned}
\sum_{i=1}^{N} \exp(-y^i f'(x^i)) &= \sum_{i=1}^{M} \exp(-y^i [f(x^i) + \alpha h(x^i)]) \\
&\simeq \sum_{i=1}^{N} \exp(-y^i f(x^i))[1 - \alpha y^i h(x^i) + \frac{\alpha^2}{2}(y^i)^2 h^2(x^i)] \\
&= \sum_{i=1}^{N} \exp(-y^i f(x^i))[1 - \alpha y^i h(x^i) + \frac{\alpha^2}{2}] \\
&= Z \sum_{i=1}^{N} \underbrace{\frac{\exp(-y^i f(x^i))}{Z}}_{D^i} [1 - \alpha y^i h(x^i) + \frac{\alpha^2}{2}]
\end{aligned}$$

- Choice of h: minimize $\epsilon = \sum D^i y^i h(x^i)$
- Choice of a : minimize $\sum_{i=1}^{N} D^i \exp(-\alpha y^i h(x^i))$

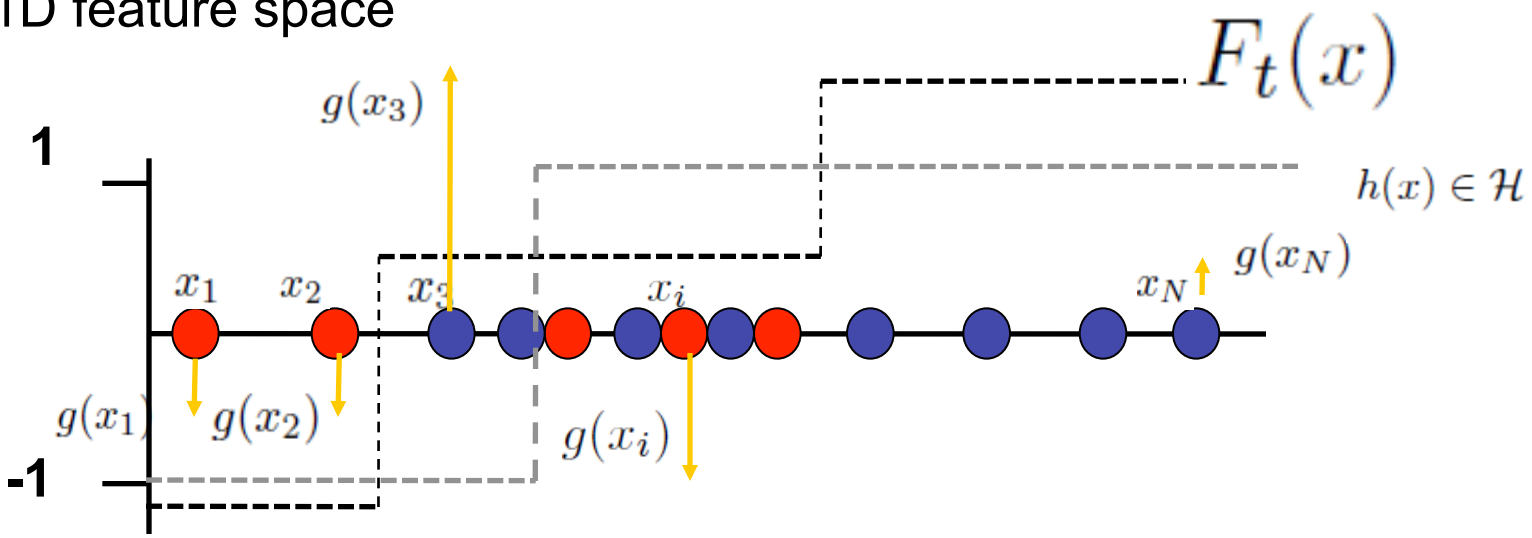
Loss functions



- z: y*f(x)
- Ideal misclassification cost H(-z) (# training errors)
- Exponential Error exp(-z) (Adaboost)
- Cross Entropy error ln(1 + exp(-z)) (Logistic regression)
- Hinge loss max(0,1-z) (SVMs)

Anyboost- I

1D feature space



Anyboost -II

Additive form: $F_t(x) = a_1 f_1(x) + \ldots + a_t f_t(x) \quad a_t \in R, f_t \in \mathcal{H}$

At each round, add optimal pair $(a_{t+1}, f_{t+1}(x))$

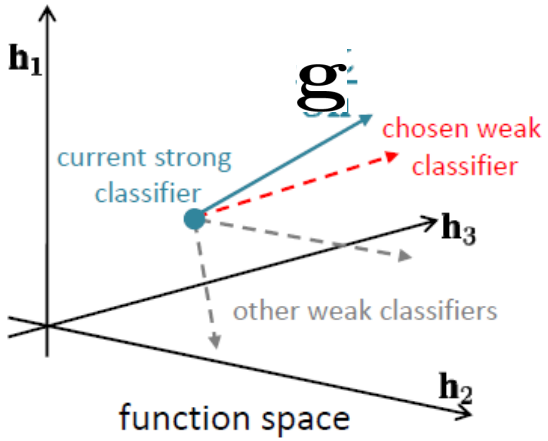
See training cost as function of $\mathbf{F} = (F_t(x^1), \ldots, F_t(x^N))^T$

Steepest descent direction: $\mathbf{g} = \left(-\frac{\partial L}{\partial \mathbf{F}_1}, \ldots, -\frac{\partial L}{\partial \mathbf{F}_N} \right)^T$

Find $f \in \mathcal{H}$ 'closest' to $\mathbf{g}$

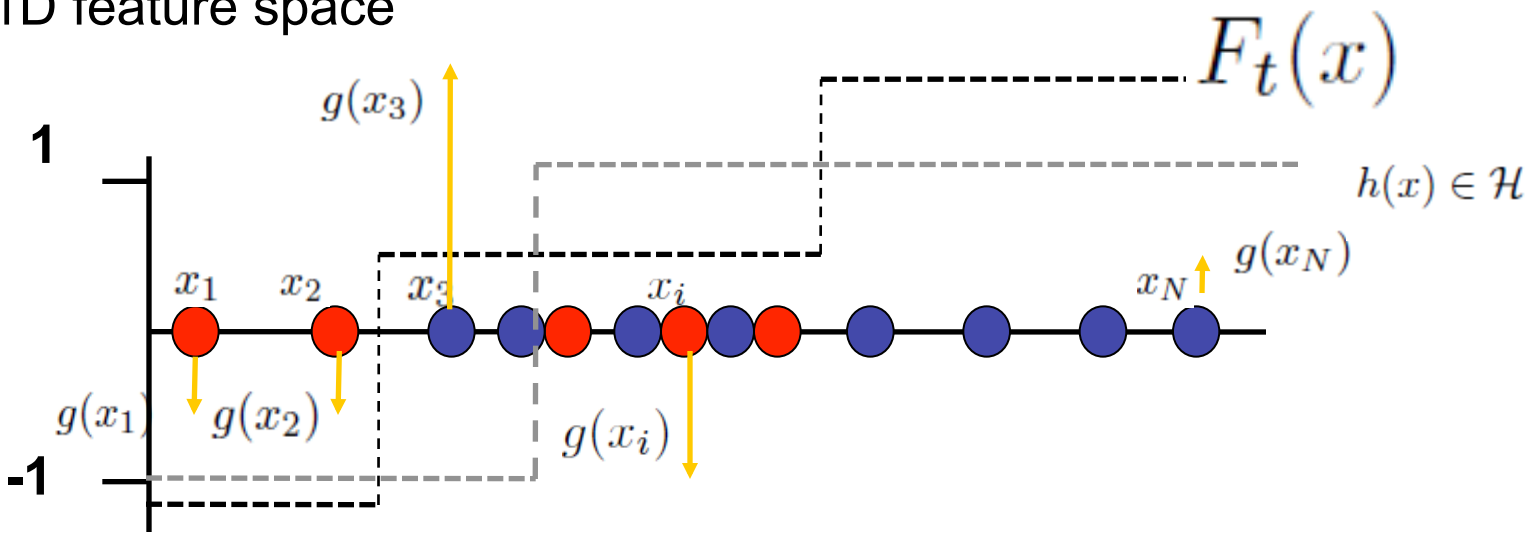
$$f_{t+1} = \text{argmax}_{f \in \mathcal{H}} \mathbf{f}^T \mathbf{g}$$

$$\mathbf{f} = (f(x^1), \ldots, f(x^N))^T$$



Anyboost- III

1D feature space



Adaboost: Anyboost for exponential loss

$$L(S, F_t) = \sum_{i=1}^{N} \exp(-y^i F_t(x^i)) \qquad \mathbf{g}_i = y^i \exp\left(-y^i F_t(x^i)\right)$$

$$y^i \in \{-1, 1\}$$

sign weight

Using Adaboost to compute posteriors

- Consider `Empirical distribution' of data

$$
\begin{aligned}
E_{X,Y}\exp(-yf(x)) &= \int_x \sum_y \exp(-yf(x))P(x,y)dxdy \\
&= \int_x \sum_y \exp(-yf(x))P(y|x)dyP(x)dx \\
&= \int_x [P(y=1|x)\exp(-f(x)) + P(y=-1|x)\exp(f(x))]dy]\,dx
\end{aligned}
$$

- Optimize w.r.t $f(x)$: $f(x) = \log \frac{P(y=1|x)}{P(y=-1|x)}$

- We can therefore use $f(x)$ for a probabilistic classifier

Side-by-side

Logistic regression

- Linear

$$F_a(x) = a_1 x_1 + \ldots + a_K x_K$$

- Summands: features
  - fixed
- a: Newton-Raphson
- Cost: minus label log likelihood

Anyboost

- Additive

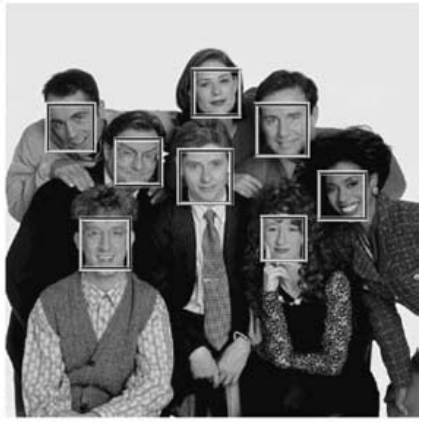
$$F_t(x) = a_1 f_1(x) + \ldots + a_t f_t(x)$$

- Summands: weak learners
  - added `on the fly'
- a : Coordinate descent
- Cost: exponential loss (Adaboost)

Connections: M. Collins, R. Schapire, Y. Singer `Logistic Regression, AdaBoost and Bregman Distances' COLT (2000)

Application to Vision

- Viola & Jones, `Rapid Object Detection using a Boosted Cascade of Simple Features', CVPR 01
  - First reliable, real-time face detection system
  - Used in commercial products, e.g. digital cameras
- Sample detections (back in 2001)



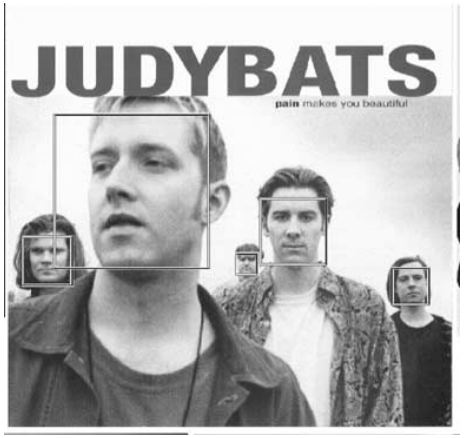


Image Features (Weak learners)

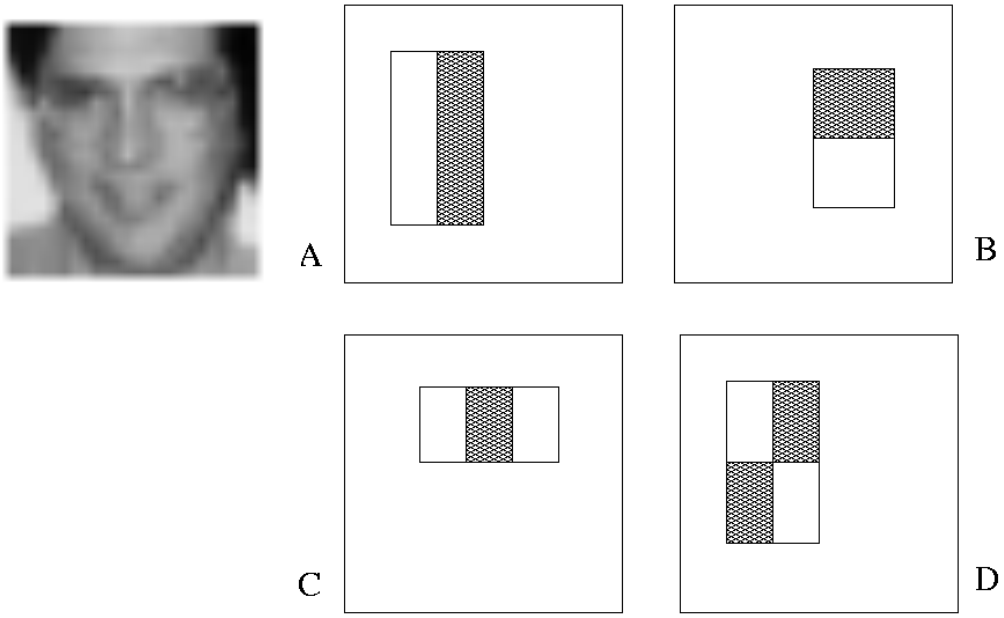
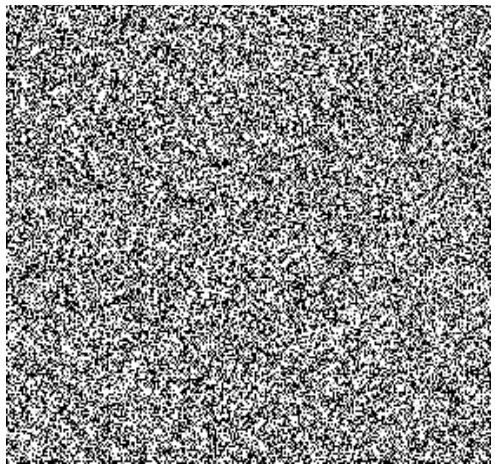
“Rectangle filters”



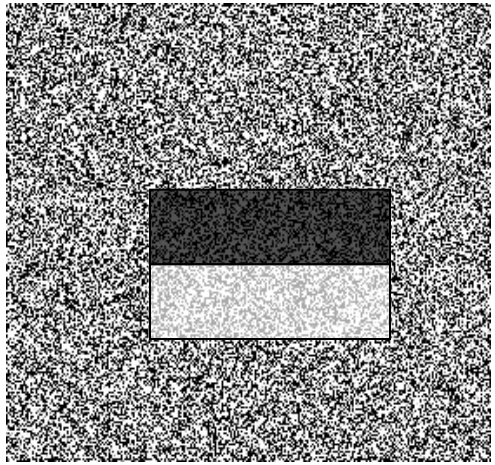
Value = $\sum$ ***(pixels in white area) –*** $\sum$ ***(pixels in black area)***

Decision stump: Threshold difference
Why these features?
Extremely fast to compute (4 pixel operations per box)

Example



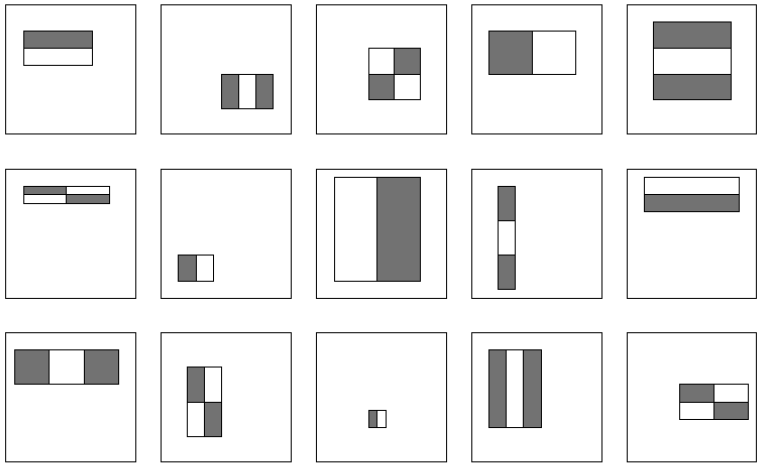
Source



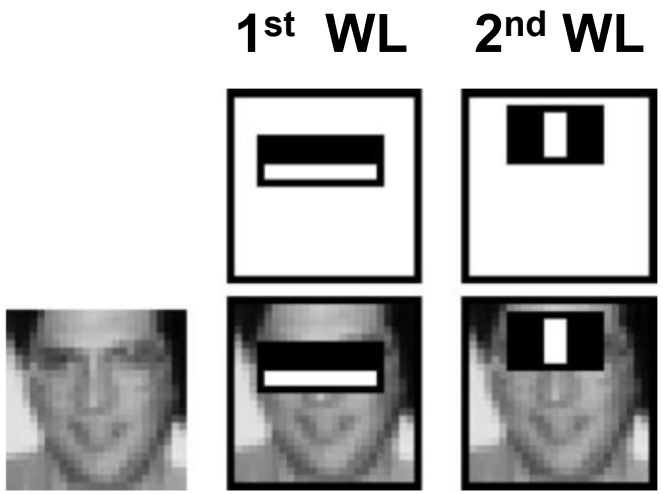
Result

Feature selection

- For a 24x24 detection region, the number of possible rectangle features is ~180,000!

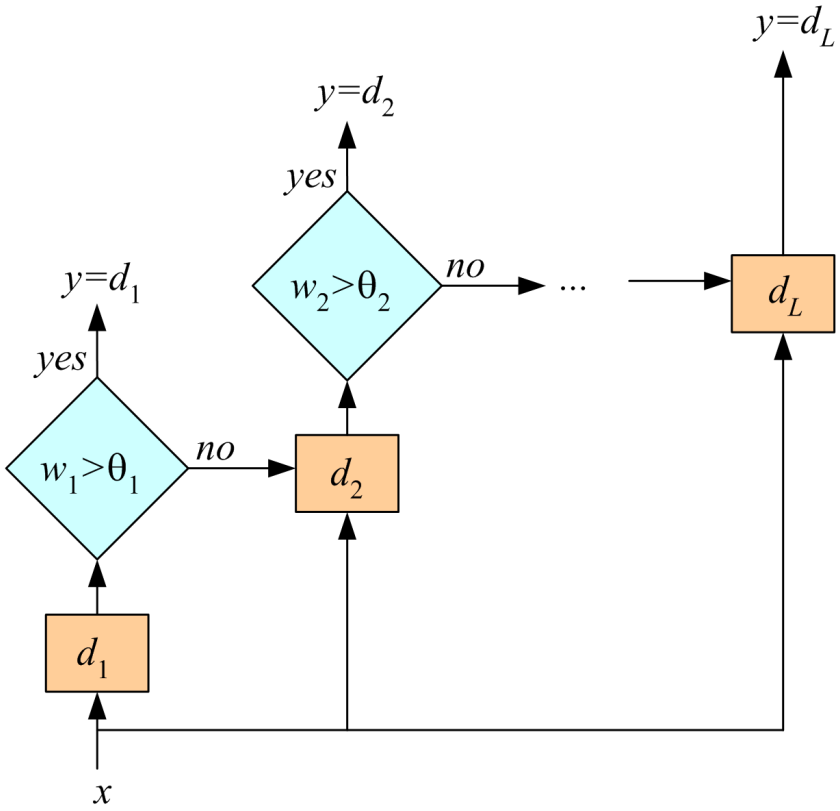


- Chosen automatically by Adaboost



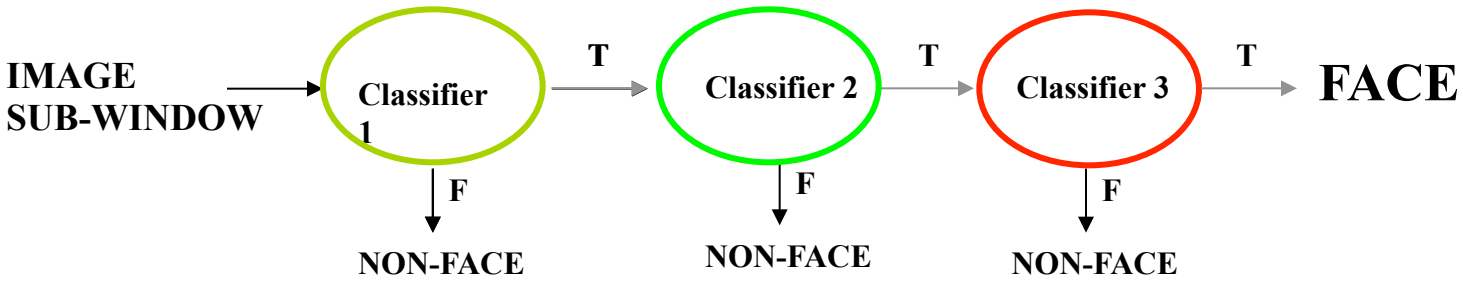
Viola & Jones: Cascade

- Reject large portions of the image based on thresholding first few weak learners



Speedup tricks

- Attentional cascade



- Integral images (4 pixel operations per filter)
- C++ implementation available in OpenCV [Lienhart, 2002]
  - http://sourceforge.net/projects/opencvlibrary/
- Matlab wrappers for OpenCV code available, e.g. here
  - http://www.mathworks.com/matlabcentral/fileexchange/19912

P. Viola and M. Jones. *Rapid object detection using a boosted cascade of simple features*. CVPR 2001.

The implemented system

- Training Data
  - 5000 faces
    - All frontal, rescaled to 24x24 pixels
  - 300 million non-faces
    - 9500 non-face images
  - Faces are normalized
    - Scale, translation
- Many variations
  - Across individuals
  - Illumination
  - Pose

P. Viola and M. Jones. *Rapid object detection using a boosted cascade of simple features*. CVPR 2001.

System performance

- Training time: “weeks” on 466 MHz Sun workstation
- 38 layers, total of 6061 features
- Average of 10 features evaluated per window on test set
- “On a 700 Mhz Pentium III processor, the face detector can process a 384 by 288 pixel image in about .067 seconds”
  - 15 Hz
  - 15 times faster than previous detector of comparable accuracy (Rowley et al., 1998)

P. Viola and M. Jones. *Rapid object detection using a boosted cascade of simple features*. CVPR 2001.

Recap

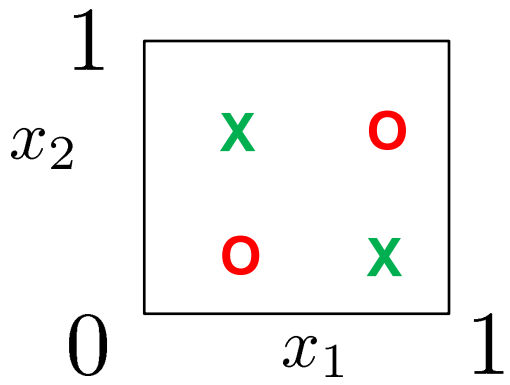
Adaboost

Decision Trees

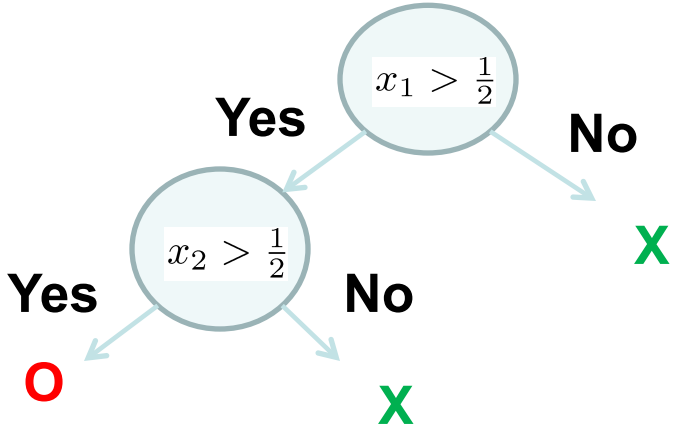
Random Forests & Ferns

Will AdaBoost always work?

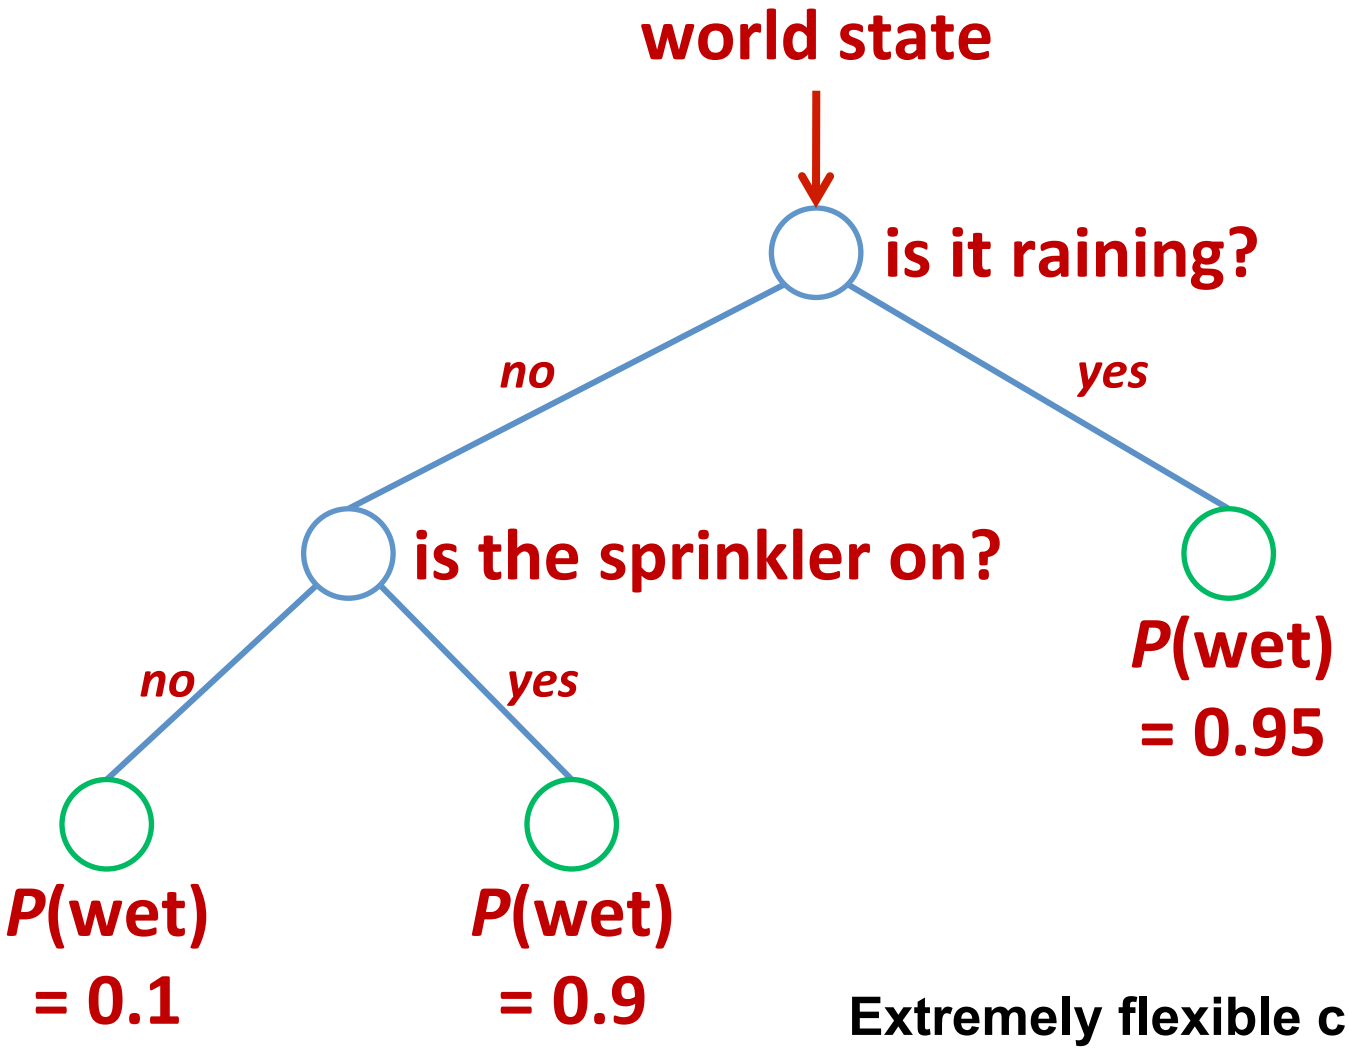
- No decision stump can separate these data with error less than 1/2



- Use classification trees (error 1/4)



Is The Grass Wet?

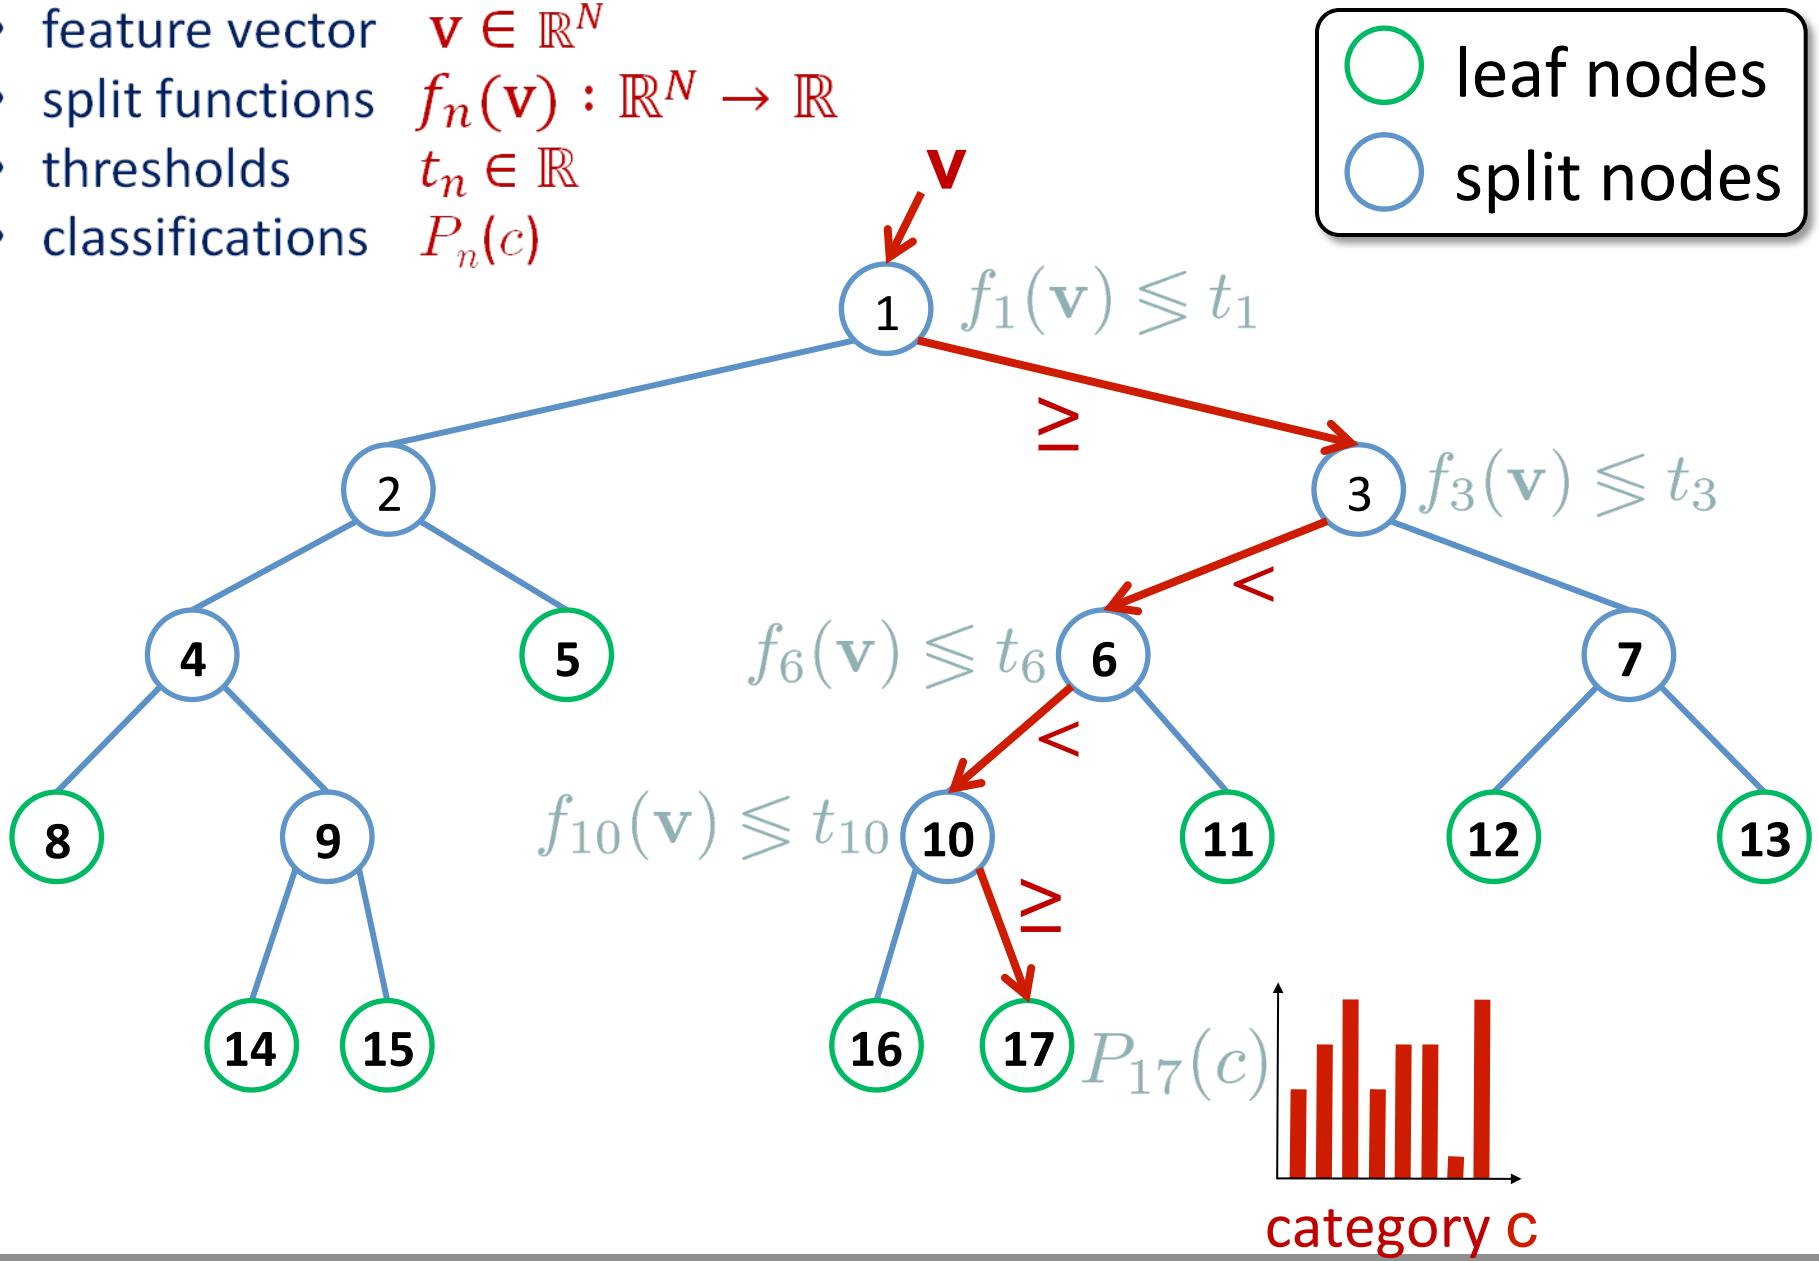


Extremely flexible classifiers!

Slide credits: J. Shotton

Binary Decision Trees

- feature vector $\mathbf{v} \in \mathbb{R}^N$
- split functions $f_n(\mathbf{v}) : \mathbb{R}^N \rightarrow \mathbb{R}$
- thresholds $t_n \in \mathbb{R}$
- classifications $P_n(c)$



Randomized Learning

- Recursively split examples at node n
  - set I_n indexes labeled training examples ($\mathbf{v}_i$, l_i):

left split → $I_l = \{i \in I_n \mid f(\mathbf{v}_i) < t\}$

right split → $I_r = I_n \setminus I_l$

threshold

function of example i's feature vector

- At node n, $P_n(c)$ is histogram of example labels l_i

More Randomized Learning

$$\begin{aligned} \text{left split } I_{\mathrm{l}} &= \{i \in I_n \mid f(\mathbf{v}_i) < t\} \\ \text{right split } I_{\mathrm{r}} &= I_n \setminus I_{\mathrm{l}} \end{aligned}$$

- Features f(v) chosen at random from feature pool f 2 F
- Thresholds t chosen in range $t \in (\min_i f(\mathbf{v}_i), \max_i f(\mathbf{v}_i))$
- Choose f and t to maximize gain in information

$$\Delta E = -\frac{|I_{\mathrm{l}}|}{|I_n|} E(I_{\mathrm{l}}) - \frac{|I_{\mathrm{r}}|}{|I_n|} E(I_{\mathrm{r}})$$

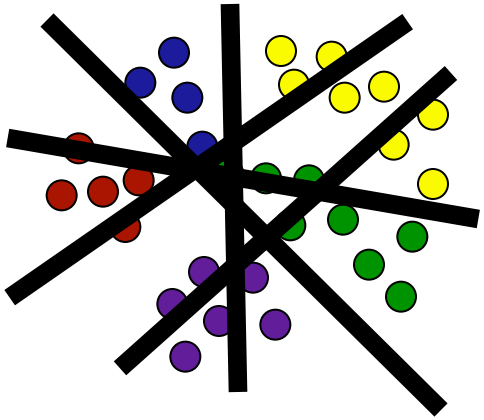
Entropy E calculated from histogram of labels in I

- Design choices: how many thresholds? Which features? When should we stop growing?

Why do random tests work?

For a small number of classes

- we can try several tests, and
- retain the best one according to some criterion.

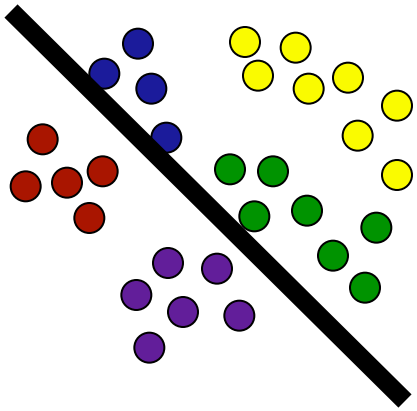


Slide credits: J. Shotton

Why do random tests work?

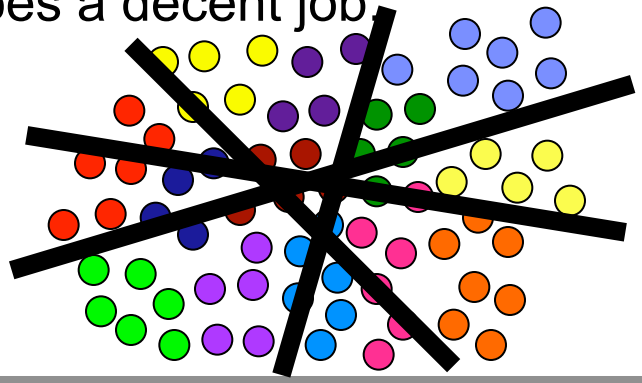
For a small number of classes

- we can try several tests, and
- retain the best one according to some criterion.



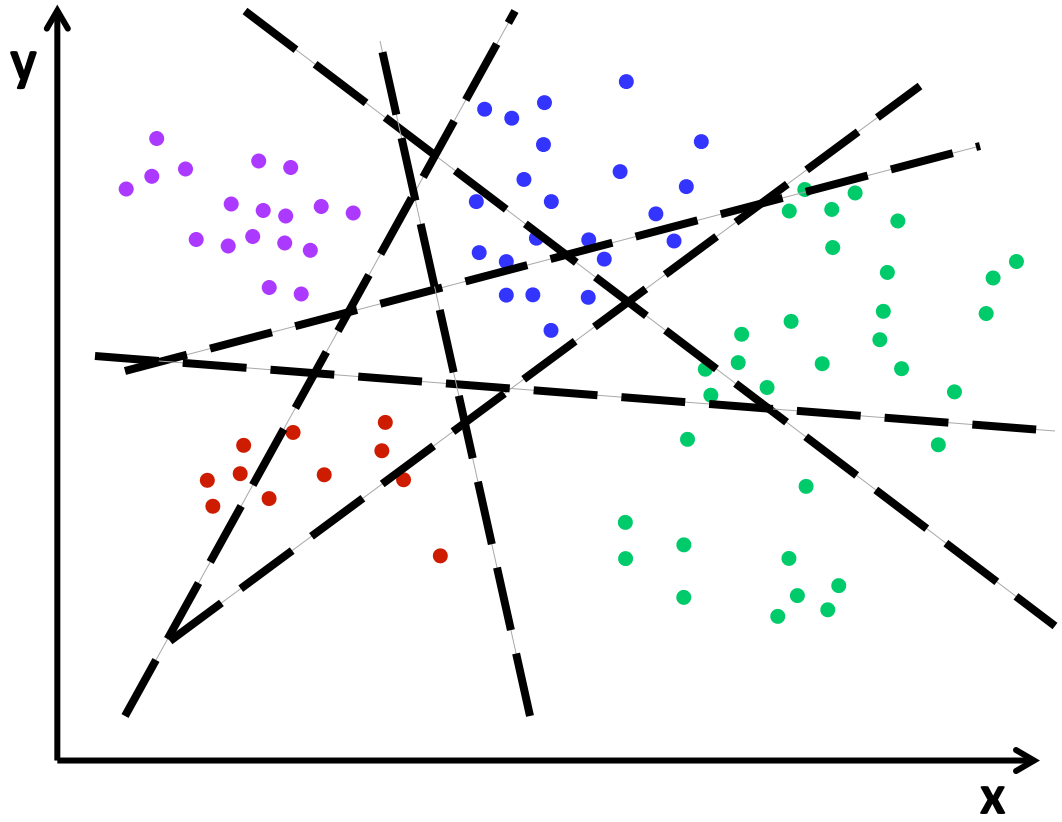
When the number of classes is large

- any test does a decent job:



Toy Learning Example

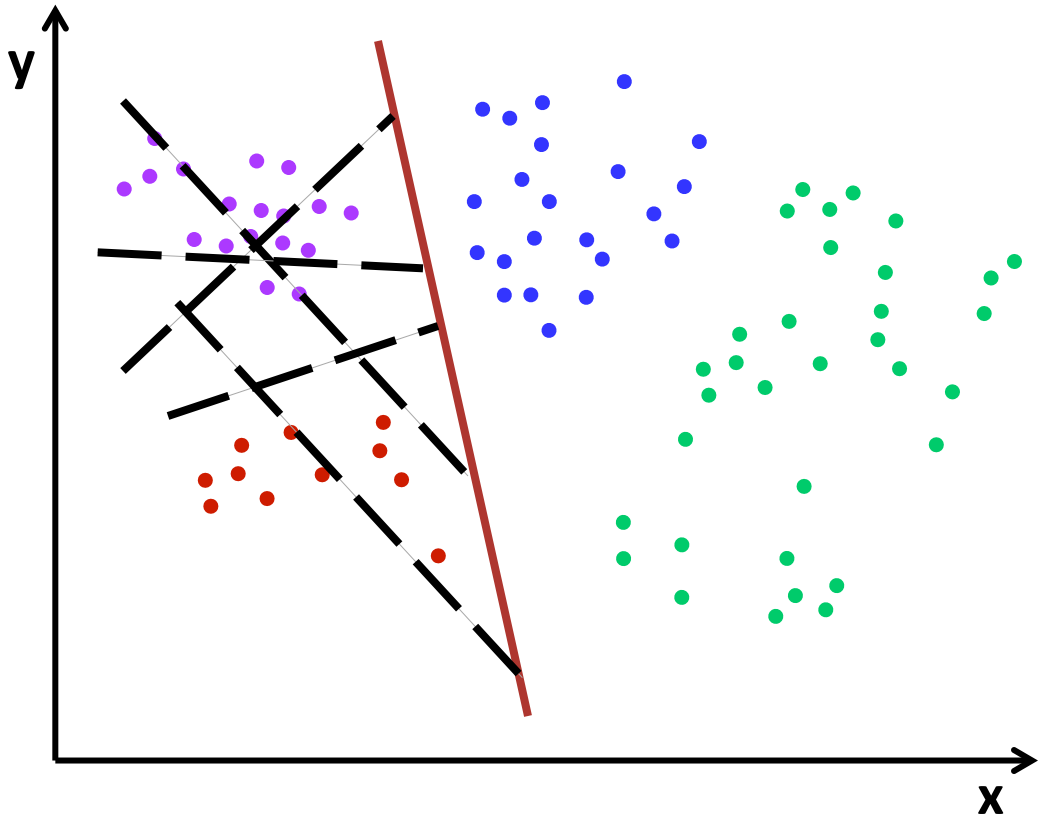
- Try several lines, chosen at random
- Keep line that best separates data
  - information gain
- Recurse



- feature vectors are x, y coordinates: $v = [x, y]^T$
- split functions are lines with parameters a, b: $f_n(v) = ax + by$
- threshold determines intercepts: t_n
- four classes: purple, blue, red, green

Toy Learning Example

- Try several lines, chosen at random
- Keep line that best separates data
  - information gain
- Recurse



- feature vectors are x, y coordinates: $v = [x, y]^T$
- split functions are lines with parameters a, b: $f_n(v) = ax + by$
- threshold determines intercepts: t_n
- four classes: purple, blue, red, green

- split functions are lines with parameters a, b: $f_n(v) = ax + by$
- threshold determines intercepts: t_n
- four classes: purple, blue, red, green

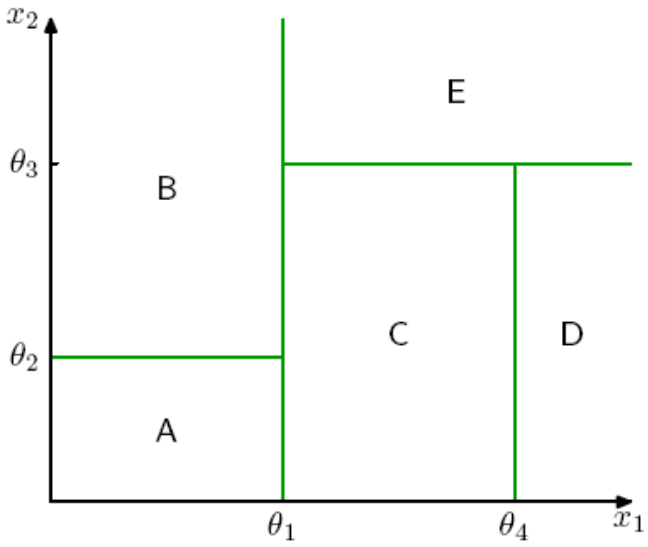
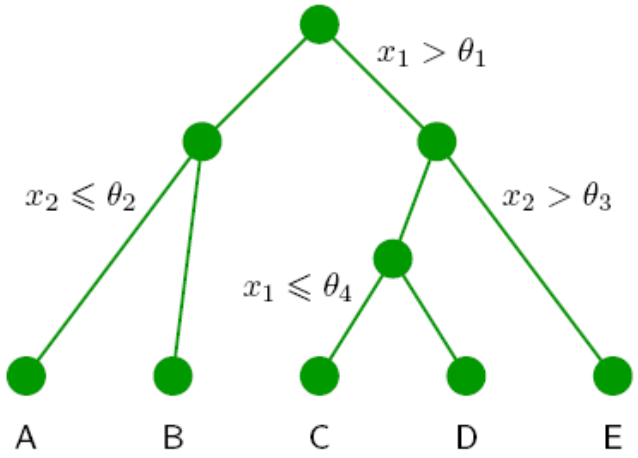
Which level of classification tree?

- Deeper trees result in more complex classifiers





- After some point overfitting occurs

Binary Decision Trees Summary

- Fast greedy training algorithms
  - can search infinite pool of features
  - heterogeneous pool of features
- Fast testing algorithm
- Needs careful choice of hyper-parameters
  - maximum depth
  - number of features and thresholds to try
- Prone to over-fitting

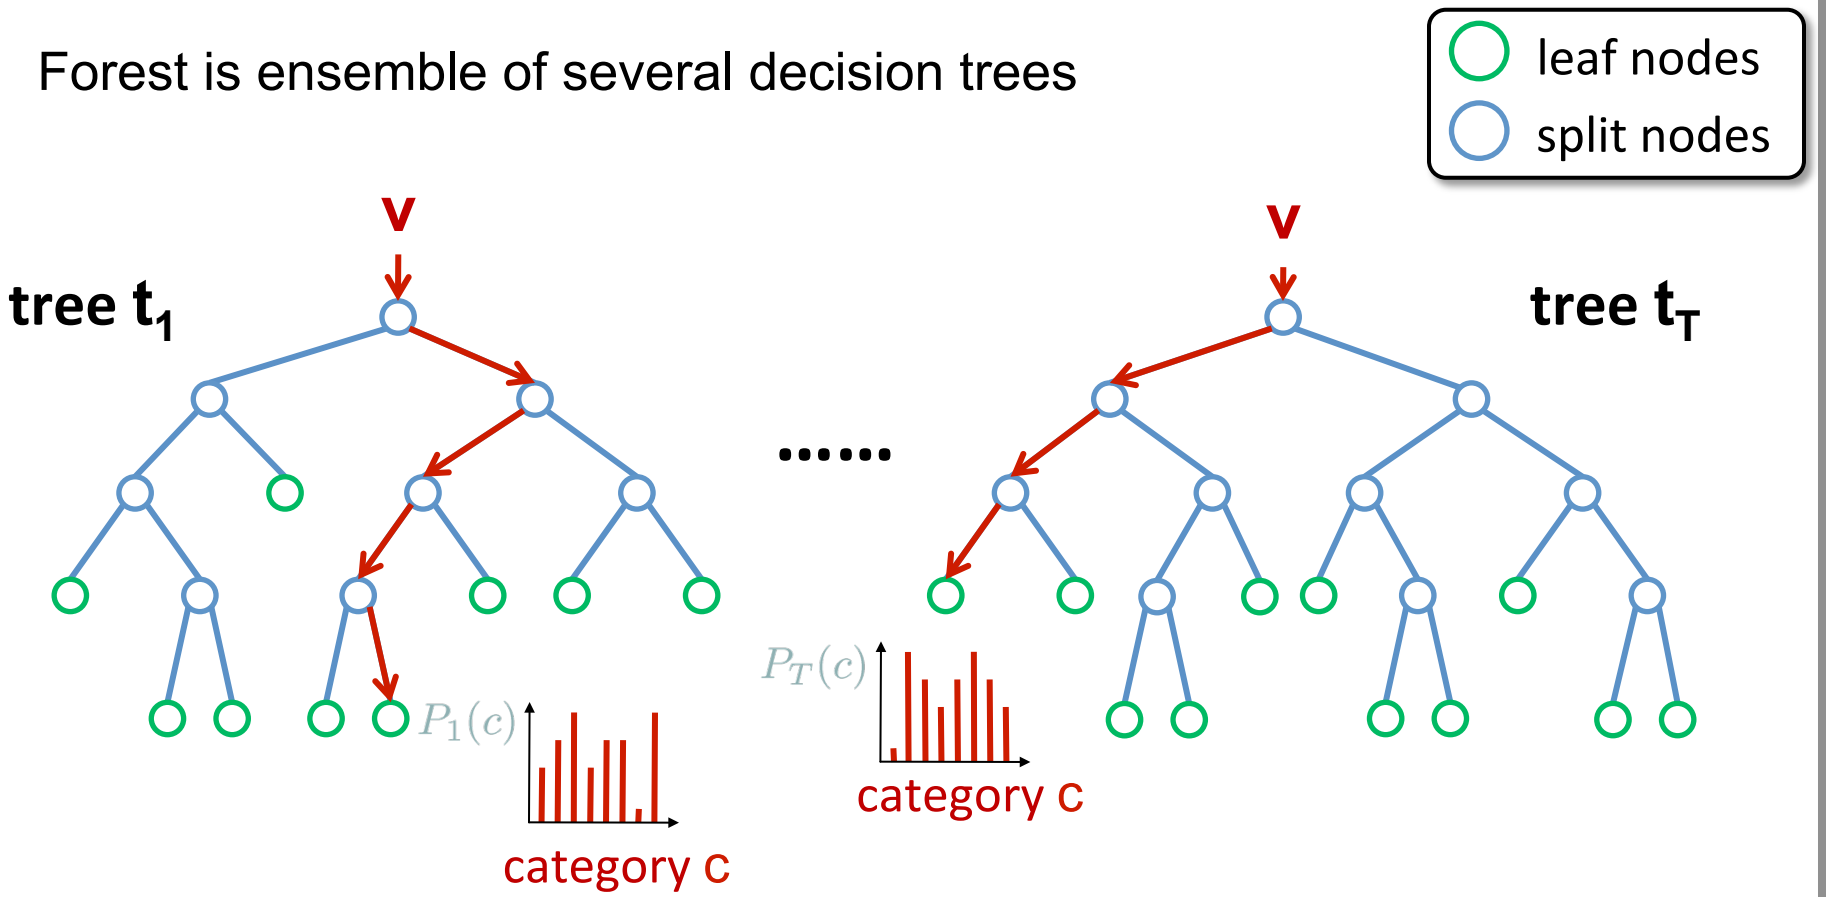
A Forest of Trees

- Forest is ensemble of several decision trees



– classification is $$P(c|\mathbf{v}) = \frac{1}{T} \sum_{t=1}^{T} P_t(c|\mathbf{v})$$

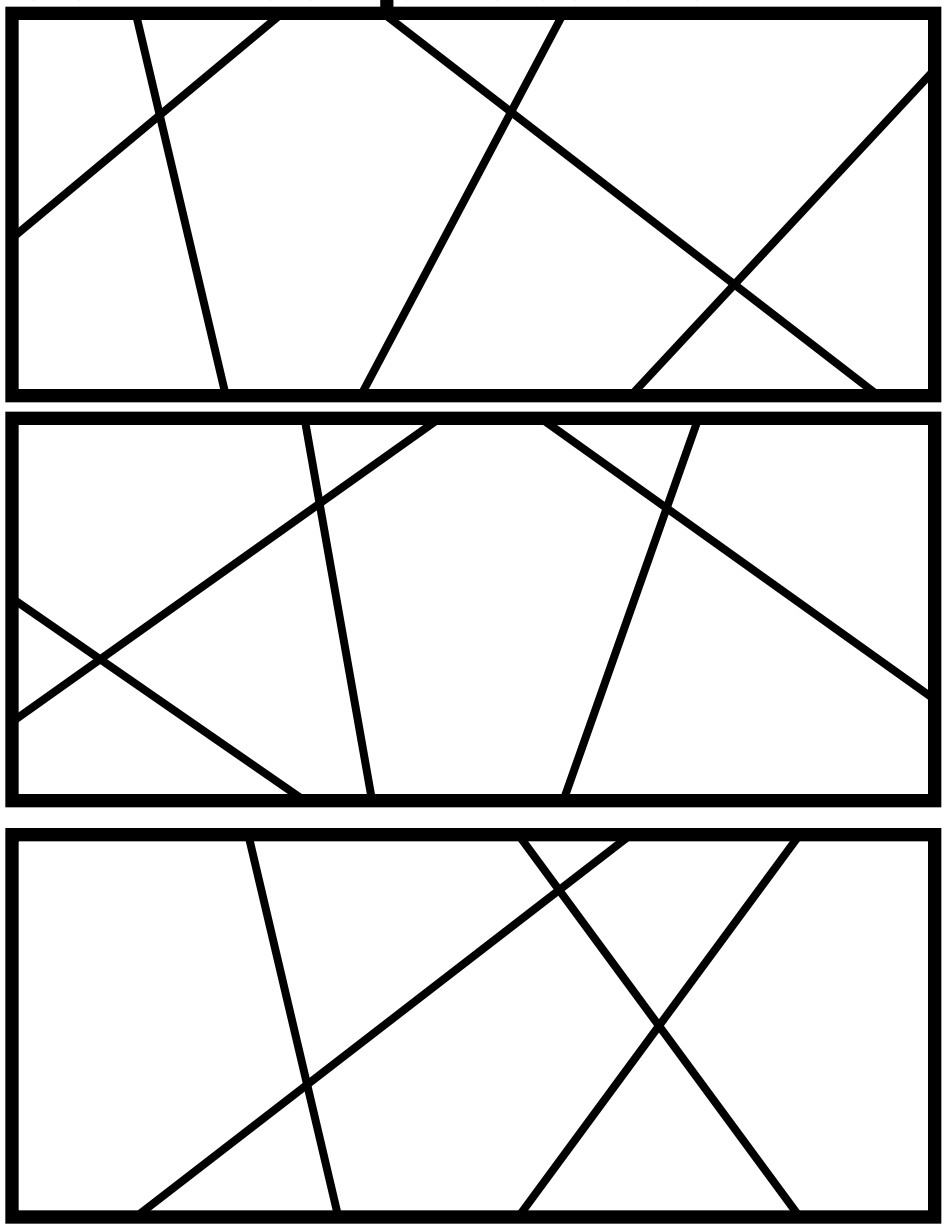
[Amit & Geman 97]
[Breiman 01]
[Lepetit *et al.* 06]

Slide credits: J. Shotton

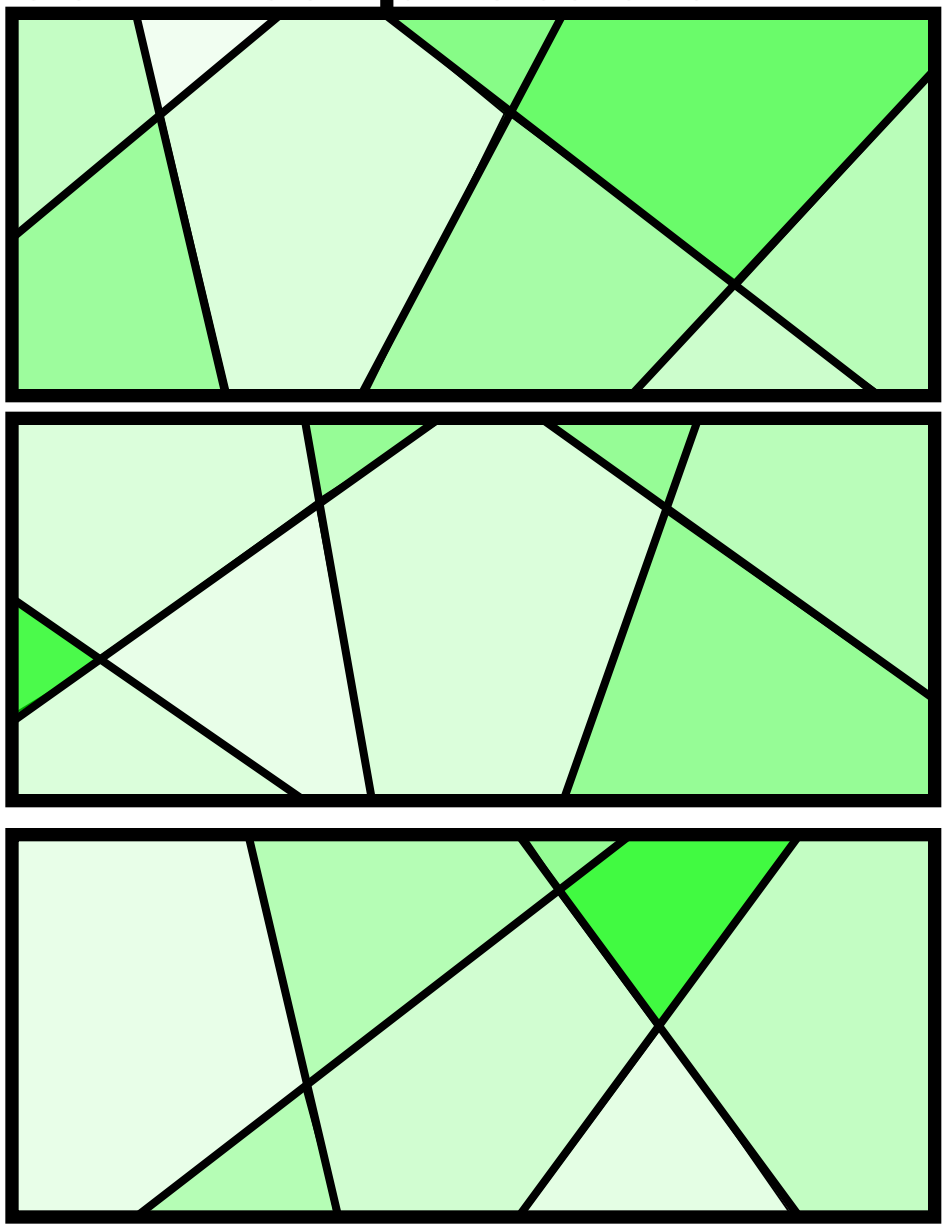
Learning a Forest

- Divide training examples into T subsets I_t
  - **improves generalization**
  - reduces **memory requirements** & **training time**
- Train each decision tree t on subset I_t
  - same decision tree learning as before

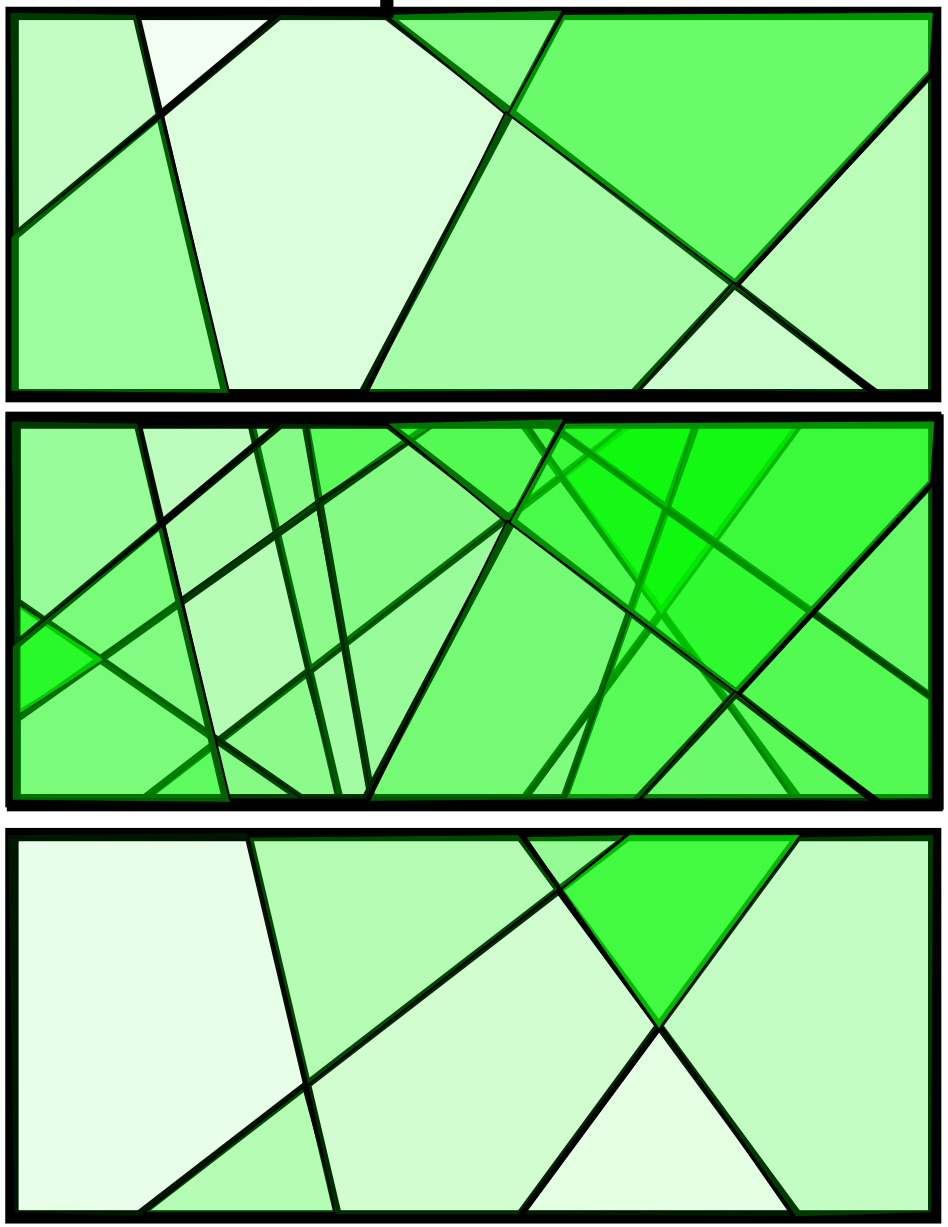
A Graphical Interpretation



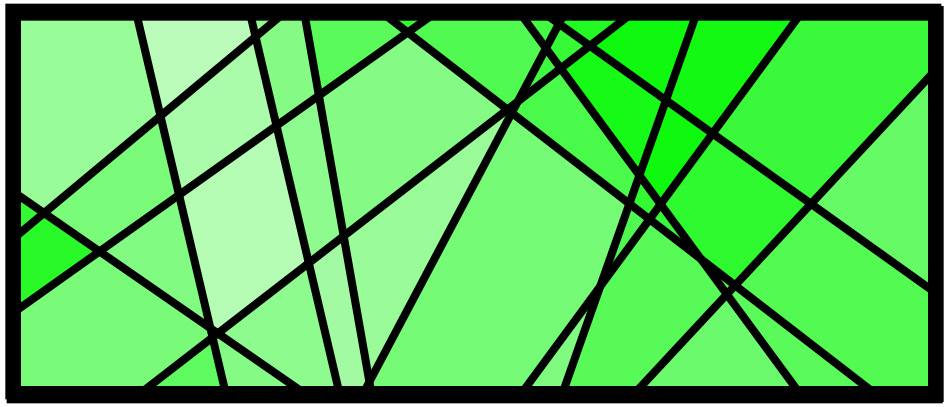
A Graphical Interpretation



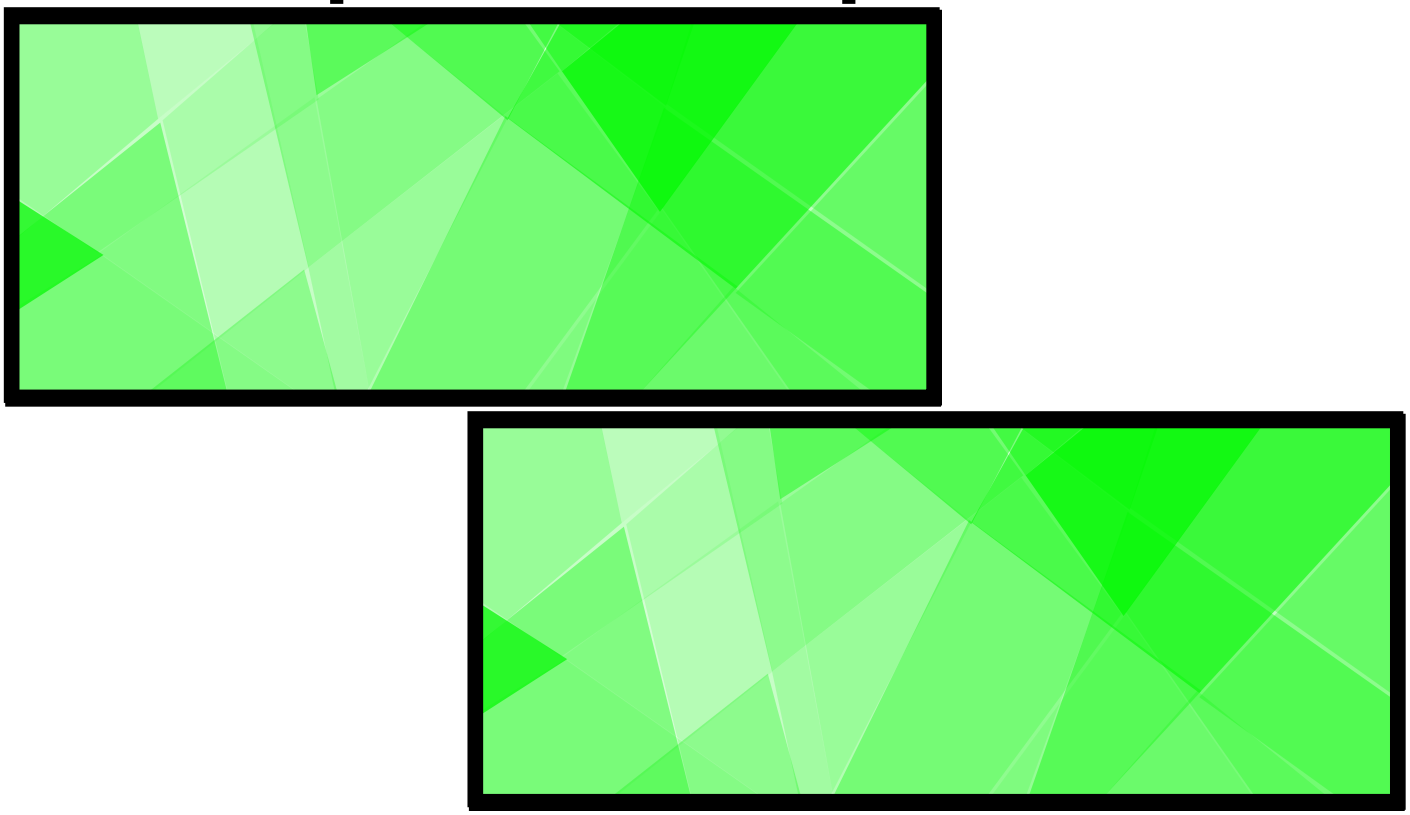
A Graphical Interpretation



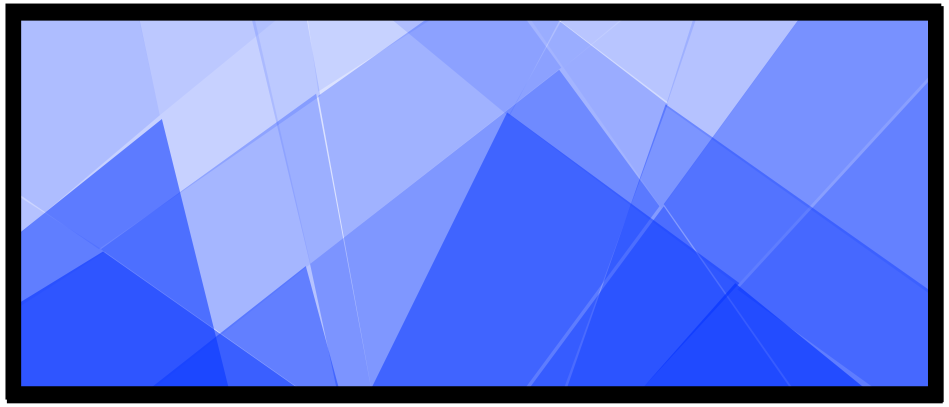
A Graphical Interpretation



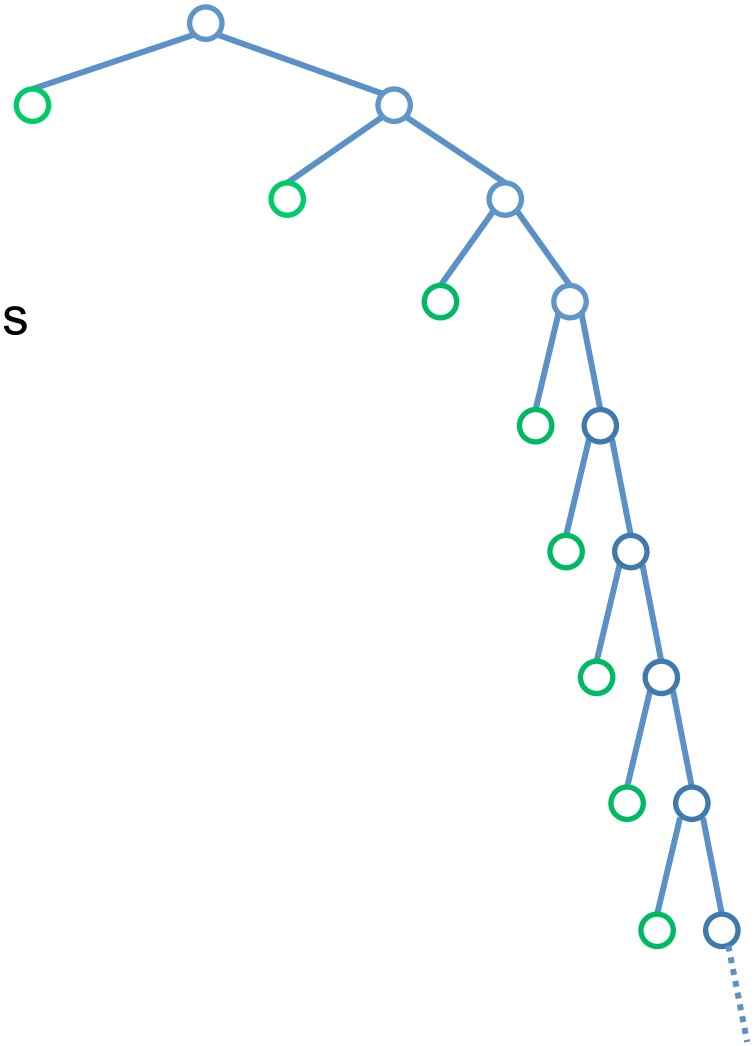
A Graphical Interpretation



A Graphical Interpretation



Relation to Cascades [Viola & Jones 04]



- Boosted Cascades
  - very unbalanced tree
  - good for unbalanced binary problems
    e.g. sliding window object detection

- Randomized forests
  - less deep, fairly balanced
  - ensemble of trees gives robustness
  - good for multi-class problems

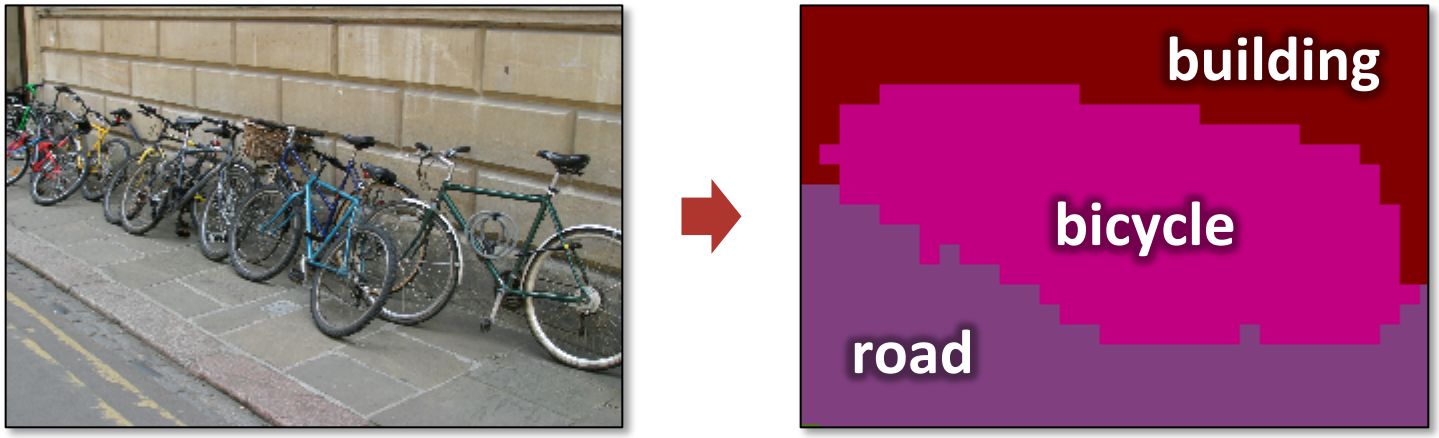
Example Semantic Texton Forest

Input Image

Ground Truth

Segmentation Forest

- Object segmentation



Real-Time Object Segmentation [Shotton *et al.* 2008]

Kinect's pipeline

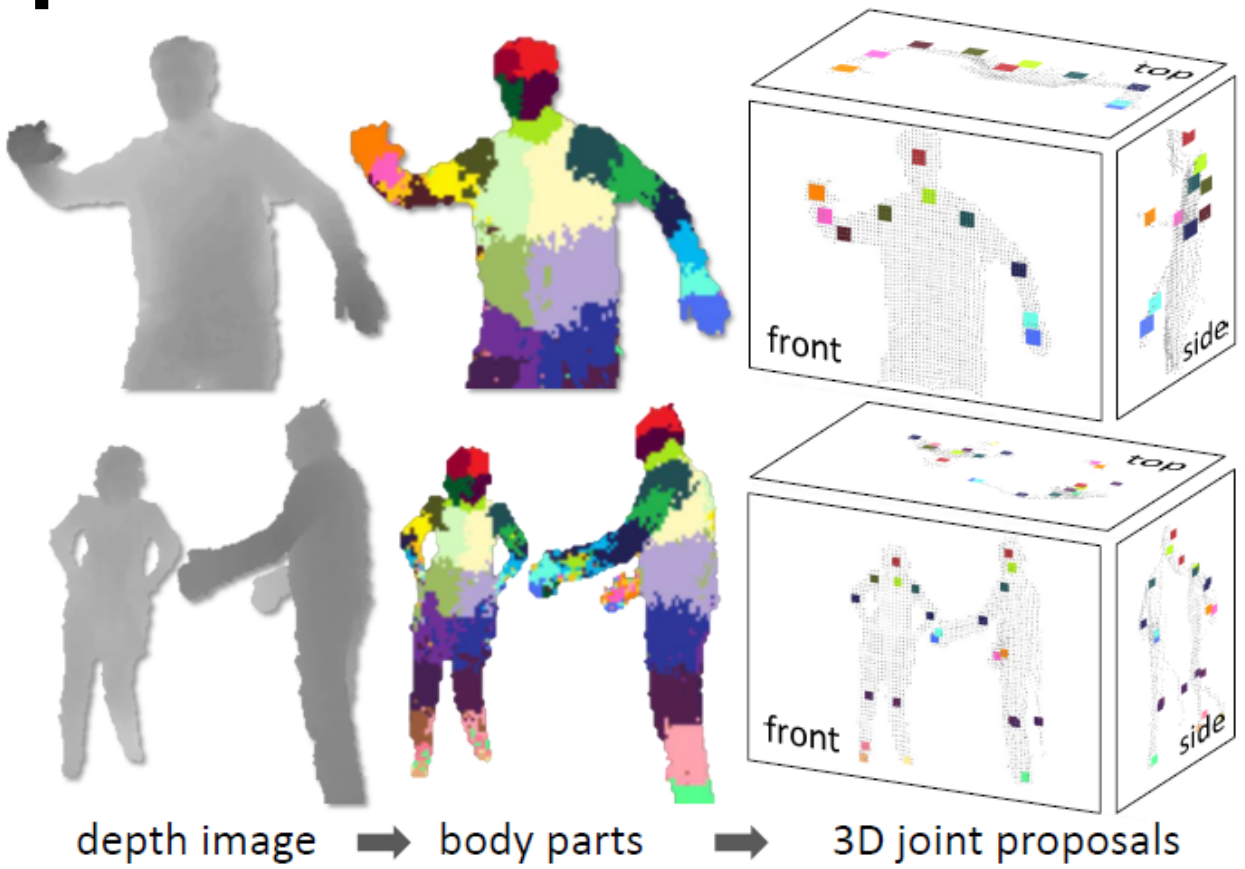

Figure 1. **Overview.** From an single input depth image, a per-pixel body part distribution is inferred. (Colors indicate the most likely part labels at each pixel, and correspond in the joint proposals). Local modes of this signal are estimated to give high-quality proposals for the 3D locations of body joints, even for multiple users.

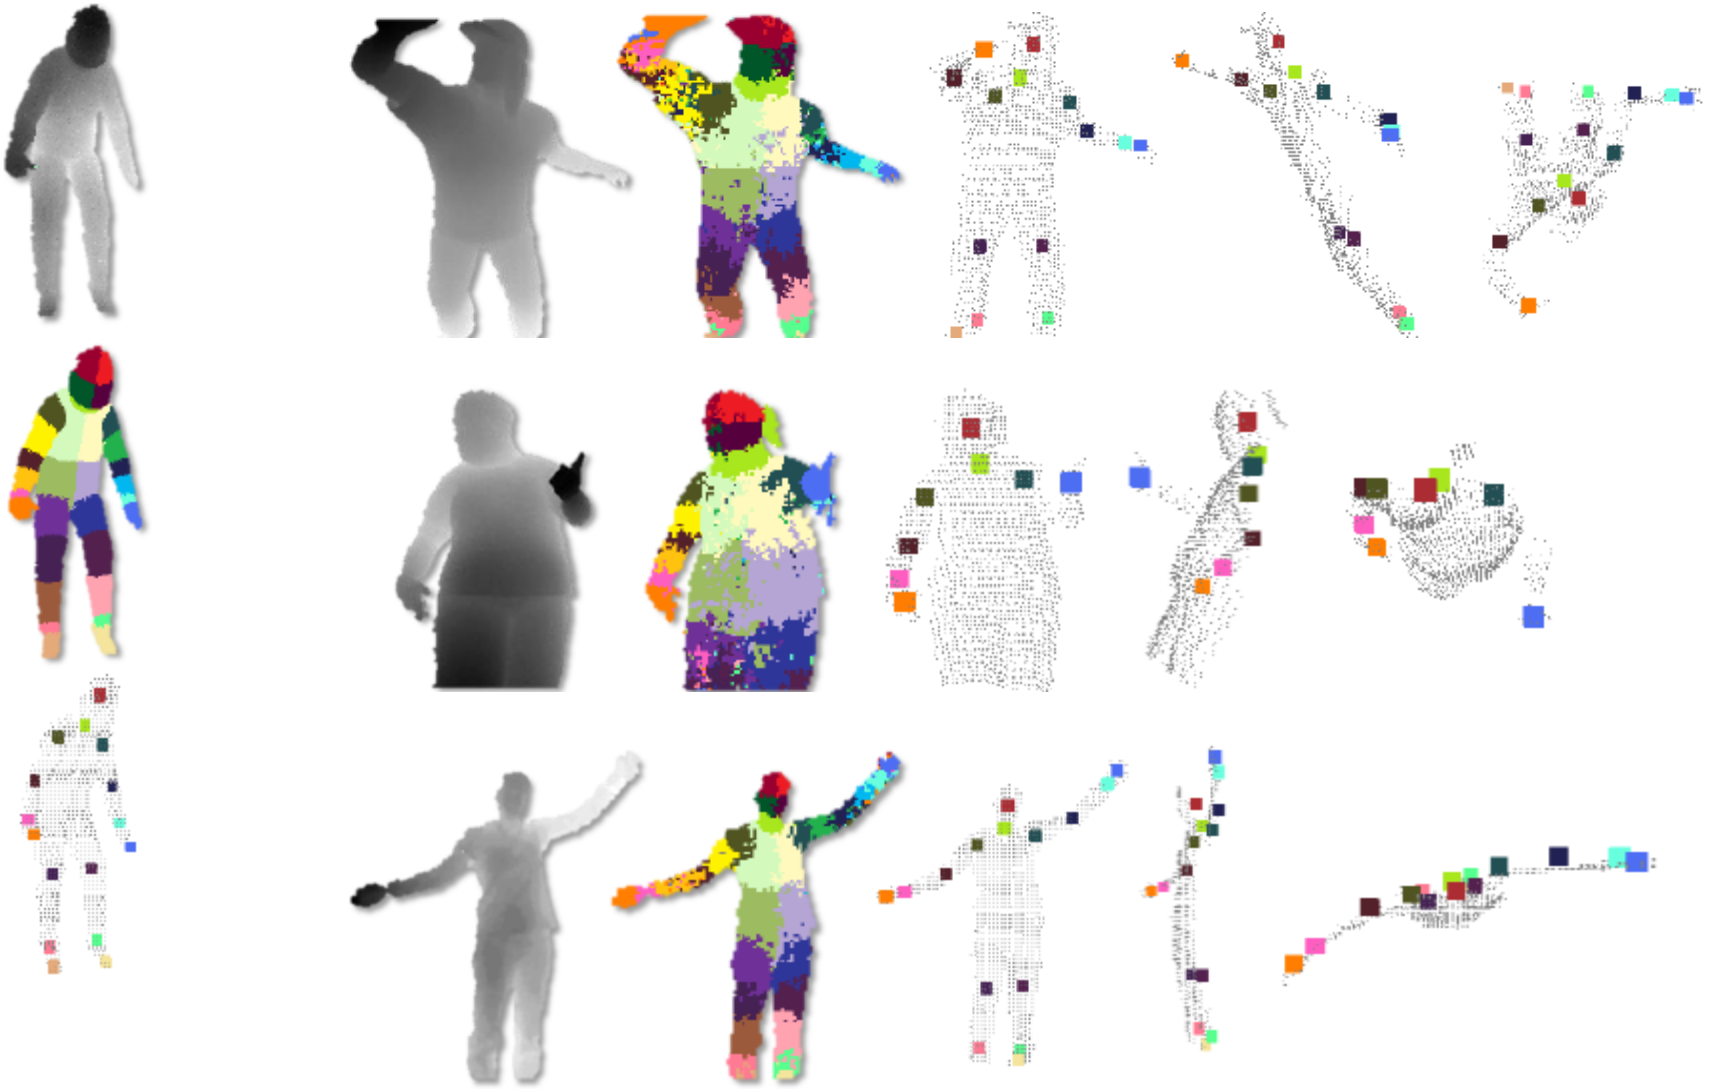
- Jamie Shotton, Andrew Fitzgibbon, Mat Cook, Toby Sharp, Mark Finocchio, Richard Moore, Alex Kipman, and Andrew Blake,
Real-Time Human Pose Recognition in Parts from a Single Depth Image, in *CVPR*, IEEE, June 2011

- **Abstract:** We propose a new method to quickly and accurately predict 3D positions of body joints from a single depth image, using no temporal information. We take an object recognition approach, designing an intermediate body parts representation that **maps the difficult pose estimation problem into a simpler per-pixel classification problem.** Our **large and highly varied training dataset** allows the classifier to estimate body parts invariant to pose, body shape, clothing, etc. Finally we generate confidence-scored 3D proposals of several body joints by reprojecting the classification result and finding local modes.
- **The system runs at 200 frames per second on consumer hardware**. Our evaluation shows high accuracy on both synthetic and real test sets, and investigates the effect of several training parameters. We achieve state of the art accuracy in our comparison with related work and demonstrate improved generalization over exact whole-skeleton nearest neighbor matching.



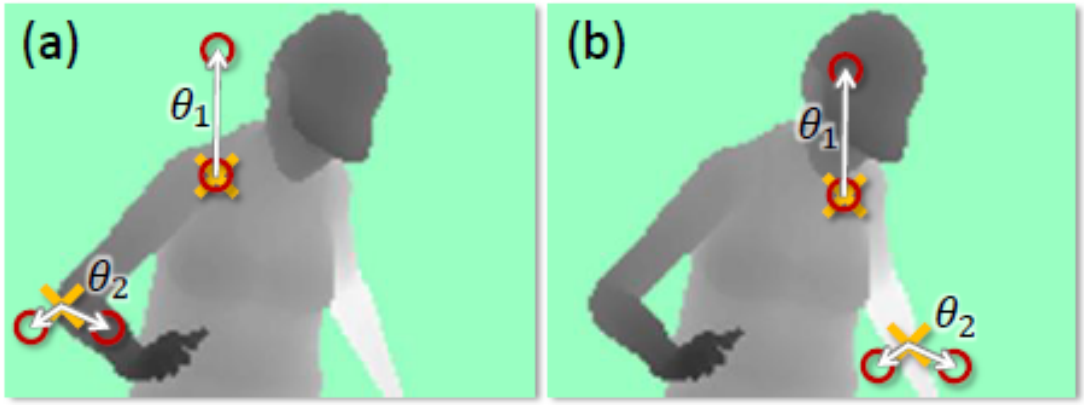


Figure 3. **Depth image features.** The yellow crosses indicates the pixel x being classified. The red circles indicate the offset pixels as defined in Eq. 1. In (a), the two example features give a large depth difference response. In (b), the same two features at new image locations give a much smaller response.

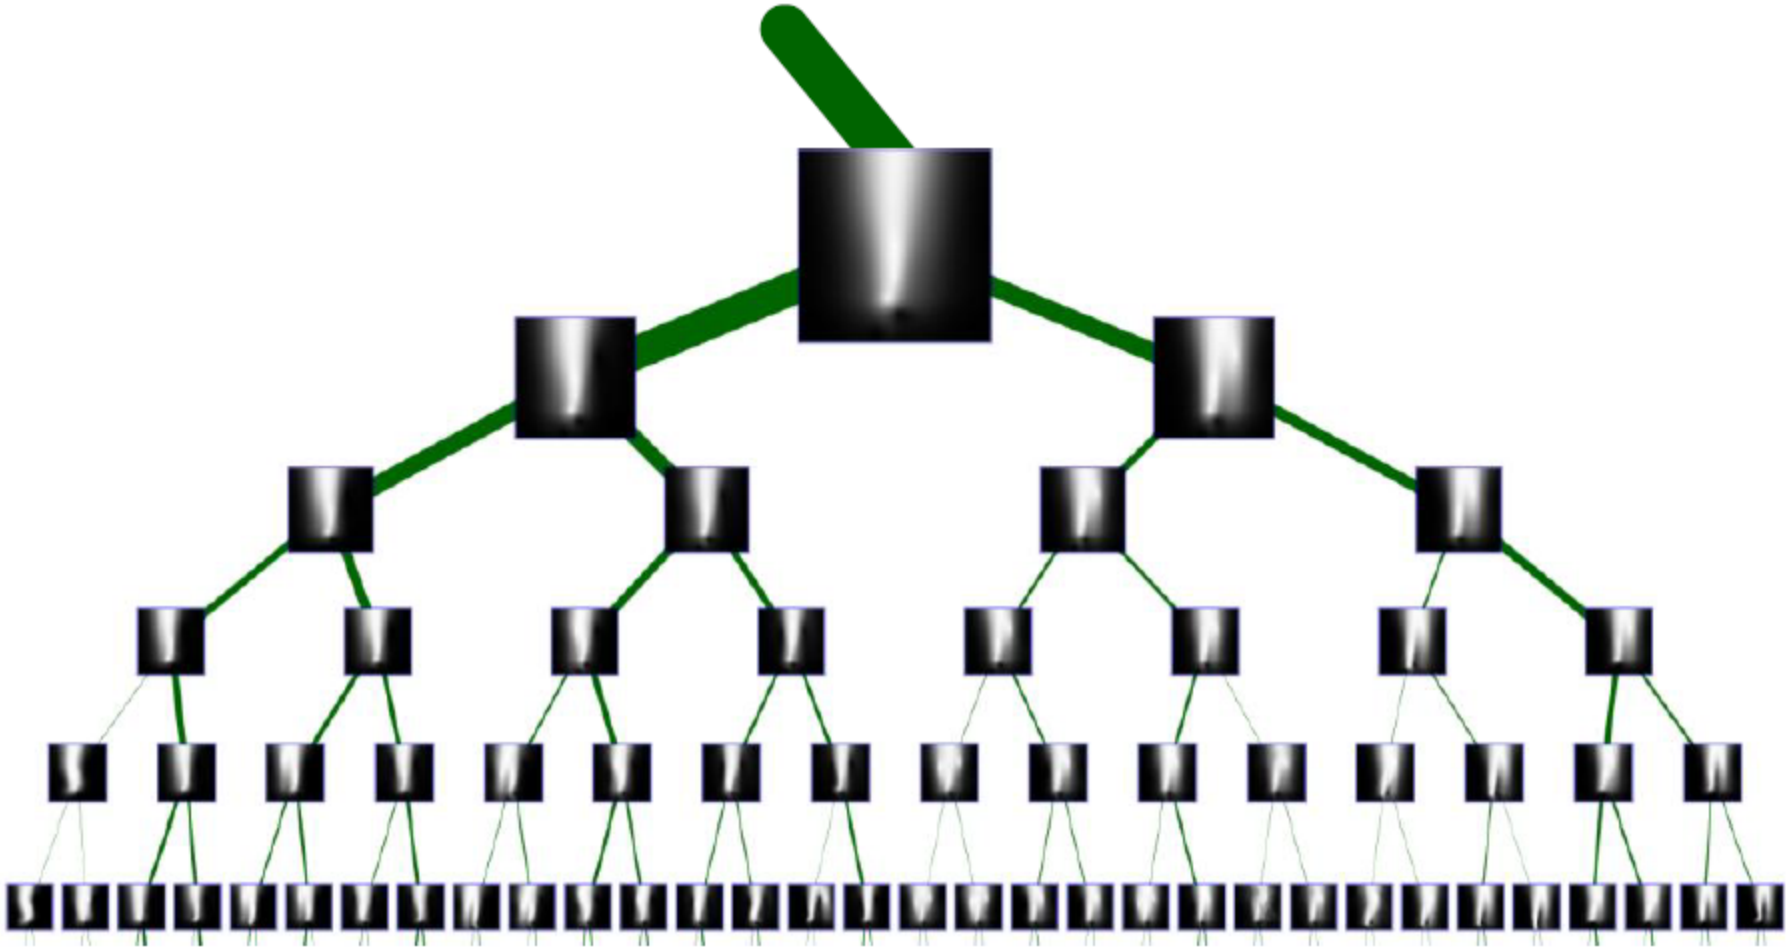

Figure 11. **Visualization of a trained decision tree.** Two separate subtrees are shown. A depth image patch centered on each pixel is taken, depth normalized, and binarized to a foreground/background silhouette. The patches are averaged across all pixels that reached any given tree node. The thickness of the edges joining the tree nodes is proportional to the number of pixels, and here shows fairly balanced trees. All pixels from 15k images are used to build the visualization shown.

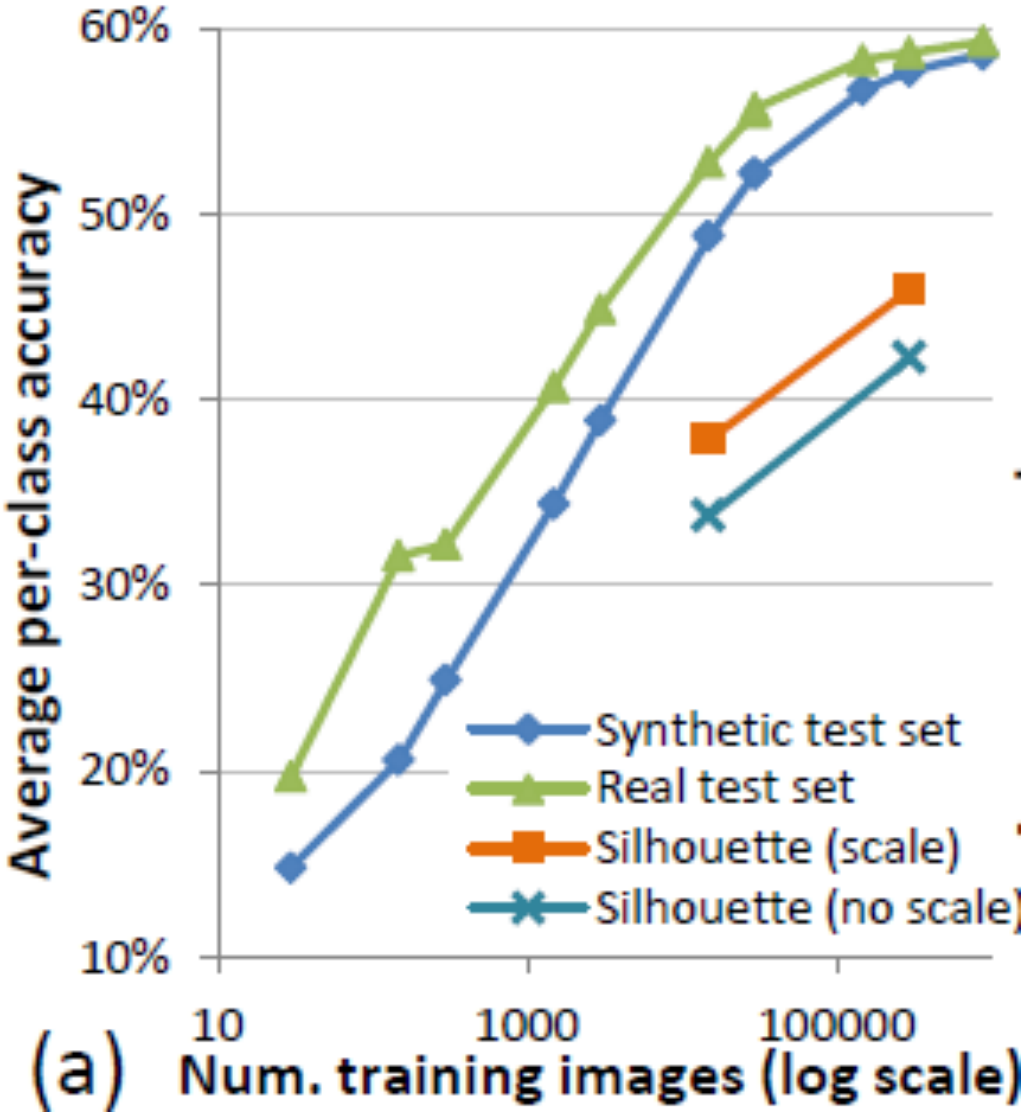
Why the class is not over yet



Appendix: F-measure optimization with boosting

Training set $S = \{(x^i, y^i)\}\ i = 1, \ldots, N \qquad x^i \in \mathcal{X},\ y^i \in \{0, 1\}$

Classifier $F : \mathcal{X} \rightarrow \{0, 1\}$

Loss $L(S, F)$

additive $L(\{(x^i, y^i)\}, F) = \sum_{i=1}^{N} l(F(x^i), y^i)$

non-additive: F-measure, Area Under Curve (AUC),…

- potentially better suited for the problem

- but also potentially non-convex (local optimality)

F-measure

Goal: deal with unbalanced datasets (many negative)

no reward for true negative decisions

Predicted label $\hat{y}^i = \left[F(x^i) > \frac{1}{2} \right]$

$$t = \sum_{i=1}^{N} [y^i = 1][\hat{y}^i = 1] \quad m = \sum_{i=1}^{N} [y^i = 1][\hat{y}^i = 0] \quad f = \sum_{i=1}^{N} [y^i = 0][\hat{y}^i = 1]$$

true positives misses false alarms

$$p = \frac{\#\text{true positives}}{\#\text{detected}} = \frac{t}{t+f} \qquad r = \frac{\#\text{true positives}}{\#\text{true}} = \frac{t}{t+m}$$

precision recall

F-measure: geometric mean of precision and recall

$$\mathcal{F} = \frac{2}{\frac{1}{p} + \frac{1}{r}} = \frac{pr}{p+r} = 2\frac{t}{t + \frac{1}{2}(f+m)}$$

F-measure approximation

predicted label

$$\hat{y}^i = \left[F(x^i) > \frac{1}{2} \right]$$

differentiable approximation

$$\tilde{y}^i = \frac{1}{1 + \exp(-F(x^i))} = \sigma(F(x^i))$$

approximate F-measure

$$\tilde{\mathcal{F}} = \frac{\tilde{t}}{\tilde{t} + \frac{1}{2}(\tilde{f} + \tilde{m})}$$

$$\tilde{t} = \sum_{i=1}^{N} [y^i = 1] \tilde{y}^i \qquad \tilde{m} = \sum_{i=1}^{N} [y^i = 1](1 - \tilde{y}^i) \qquad \tilde{f} = \sum_{i=1}^{N} [y^i = 0] \tilde{y}^i$$

F-measure optimization via Anyboost

Previous iteration $F_t(x) = a_1 f_1(x) + \ldots + a_t f_t(x)$

Loss $L(\{x^i, y^i\}, F) = -\tilde{\mathcal{F}}$

function of responses $\mathbf{F} = (F_t(x^1), \ldots, F_t(x^N))^T$

Anyboost $f_{t+1} = \text{argmax}_{f \in \mathcal{H}} \mathbf{f}^T \mathbf{g}$

$$\mathbf{f} = (f(x^1), \ldots, f(x^N))^T$$

$$\mathbf{g} = \left(-\frac{\partial L}{\partial \mathbf{F}_1}, \ldots, -\frac{\partial L}{\partial \mathbf{F}_N} \right)^T = \left(\frac{\partial \tilde{\mathcal{F}}}{\partial \mathbf{F}_1}, \ldots, \frac{\partial \tilde{\mathcal{F}}}{\partial \mathbf{F}_N} \right)^T$$

$$\mathbf{g}_i = \left[H[y^i = 1] - \frac{1}{2} H^2 \tilde{t} \right] \sigma'_{y_i}(\mathbf{F}_i)$$

$$H^{-1} = \sum_{i=1}^{N} [y^i = 1] + \frac{1}{2}(\tilde{t} + \tilde{f}) \qquad \sigma_{y^i}(\mathbf{F}_i) = \frac{1}{1 + \exp(-y^i F(x^i))}$$
